- 7. Step 7-Getting familiar:** At this starting point, users decide if they can use an existing mental model (maybe one used for another similar product) or if they need to start from scratch. The existing mental model may be void of useful knowledge or worse, contain the wrong knowledge. The core components missing at this stage include an understanding of the language the product uses and the actionable steps needed to complete core tasks.
- 8. Step 8-Apply simple criteria to which mental models you use.** When selecting mental models to include into your own latticework, consider whether they support you to better understand yourself and/or the world around you, so you might better effective and impactful action. Also Mental models do two things: they help you assess how things work and they help you make better decisions. Ask some Questions:
 - I. How long has this model been around?** As a general rule, mental models which have been around for a long time (such as Occam's razor) will have been subjected to a great deal of scrutiny. Time is an excellent curator, trimming away inefficient ideas. A mental model which is new may not be particularly refined or versatile. Many of our mental models originate from Ancient Greece and Rome, meaning they have to be functional to have survived this long.
 - II. Is it a representation of reality?** In other words, does it reflect the real world? Or is it based on abstractions?
 - III. Does this model apply to multiple areas?** The more elastic a model is, the more valuable it is to learn about. (Of course, be careful not to apply the model where it doesn't belong. Mind Feynman: "You must not fool yourself, and you're the easiest person to fool.")
 - IV. How did this model originate?** Many mental models arise from scientific or mathematical concepts. The more fundamental the domain, the more likely the model is to be true and lasting.
 - V. Is it based on first principles?** A first principle is a foundational concept which cannot be deduced from any other concept and must be known.
 - VI. Does it require infinite regress?** Infinite regress refers to something which is justified by principles, which themselves require justification by other principles. A model based on infinite regress is likely to

required extensive knowledge of a particular topic, and have minimal real-world application.

9. **Step 9- *Becoming proficient*:** Users begin to understand the language of the situation or text, especially if this language uses technical or unfamiliar vernacular. Understanding terminology and use of product language is one of the first building blocks that form the foundation of the model. This is also when users start to understand the step-by-step procedures required to perform basic operations to get some desired outcome. Here, they are usually learning the bread-and-butter operations of the product so they can receive enough value to motivate them to keep using it. Later, they will be able to build on this knowledge.
10. **Step 10- Make connections between mental models.** We need to know full context and not isolated facts. Rather than holding siloed mental models in your mind, consider how they interact, connect and complement one another.
11. **Step 11-Think, what light the mental model can bring on the situation, idea, text , speech etc.** Do I see the situation, idea, text, speech etc, in the new way? What new way can I see the situation? Does This Makes easier to make a decision in my life?
12. **Step 12- Think very carefully, if each chosen Mental model applicable to situation, idea, text, speech etc.**
13. **Step 13-Use the Chosen Mental Models tool.** The canvas, below, will help you to identify high-value areas where new mental models can make the biggest impact on your work and life. It also provides a simple framework to begin to embed using your chosen models.
14. **Step 14-*Mastering*:** Users build on the core step-by-step tasks they already know, expanding their knowledge to more complex or niche capabilities. If they make it this far they most likely have an accurate understanding of most or all of the language the product uses.
15. **Step 15-Regularly reassess their priorities without fear of changing them.** They don't fall prey to inertia.
16. **Step 16-Be biased toward taking action—not lazily deferring.** If they encounter a mental model they value, they make sure they use it.
17. **Step 17-Be always looking to prove yourselves wrong.** Ego should not get in the way of mental models.

18. Step 18-Accepting that all models are wrong in certain instances is not a license to ignore the facts. As a society, we should search for better answers, look for evidence, and strive to increase the accuracy of our knowledge.

- I. That's not to say all lenses (or models) apply to all problems. They don't. And it's not to say that having more lenses (or models) will be a advantage in all problems. It won't. This is why learning and applying the Great Mental Models is a process that takes some work. But the truth is, most problems are multidimensional, and thus having more lenses often offers significant help with the problems we are facing.**
- II. The more you use them, the more you will be able to build the knowledge of indicators that can trigger the use of the most appropriate model. Using and failing, as long as you acknowledge, reflect, and learn from it, is also how you build your repertoire. You need to be deliberate about choosing the models you will use in a situation. As you use them, a great practice is to record and reflect. That way you can get better at both choosing models and applying them. Take the time to notice how you applied them, what the process was like, and what the results were. Over time you will develop your knowledge of which situations are best tackled through which models. Don't give up on a model if it doesn't help you right away. Learn more about it, and try to figure out exactly why it didn't work. It may be that you have to improve your understanding. Or there were aspects of the situation that you did not consider. Or that your focus was on the wrong variable.**

- 19. Step 19-After all Analysis, decide what models are the most suitable after all to apply.**
- 20. Step 20-Apply The Mental Model in Real Life or Reality, and let the world do the work for You.**

Step 62 - Multidisciplinary Thinking

1. **Step 1 Define Multidisciplinary Thinking.** Multidisciplinary thinking taking combination of various disciplines that maintain their unique perspective unchanged. They share a connection that is not collaborative, but collective and can work together to create a more complicated picture of Reality. The topic of analysis will best expose its different characteristics by exploring different perspectives, using the techniques and observations provided by variety of developed disciplines. Multidisciplinarity is characterised within the literature as the least integrative form of integrated research—yet, equally, it is arguably the most attainable. Multidisciplinarity features several academic disciplines in a thematically based investigation with multiple goals—essentially, studies “co-exist in a context” . While researchers aim to share knowledge and compare results from the studies there is no attempt to cross boundaries or generate new integrative knowledge. Each member is able to contribute a professional perspective on the issue. Thus the advantage of this approach is that, while the research approaches are disciplinary, the different perspectives on the issue can be gathered into one report for assessment. There is some debate on the extent to which research is coordinated and integrated. While some suggest that multidisciplinary research is coordinated, but not integrated; others contend that there is no coordination, but there is integration at a low level. In general, it is hard to imagine that the research is not, in some way coordinated whilst maintaining even a slight degree of coherence, but it may indeed not be integrated. Multidisciplinary working brings disciplines together so they can learn from each other, drawing on the mix of disciplinary knowledge. It's like a salad: the original ingredients are intact, but the flavours begin to blend. Let's review the process that Pinker has laid out, one that we might think about emulating as we examine the causes of complex phenomena in human systems:

- I. We observe an interesting phenomenon in need of explanation, one we feel capable of exploring.
- II. We propose and examine competing hypotheses that would explain the phenomena (set up in a falsifiable way, in harmony with the divide between science and pseudoscience laid out for us by the great Karl Popper).
- III. We examine a cross-section of: Empirical data relating to the phenomena; sensible qualitative inference (from multiple fields/disciplines, the more fundamental the better), and finally; “Demonstrable” aspects of nature we are nearly certain about, arising from controlled experiment or other rigorous sources of knowledge ranging from engineering to biology to cognitive neuroscience.
- IV. Listen and Apply The Following Books:
 - **How we can Assess the Level of Interdisciplinarity and Transdisciplinarity of Academic Institutions? By Mahmood Ramezanzade**
 - **Detection of Distributed Denial of Service (DDoS) Attacks in IOT Based Monitoring System of Banking Sector Using Machine Learning Models By Muhsmmsf Shafiq**

2. Step 2-Do Work Required to Have an Opinion on Any Topic and Anything.

- I. Most people go through life not really getting any smarter. Why? They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
- II. You can acquire knowledge if you want it. In fact, there is a simple formula, which if followed is almost certain to make you smarter over time. Simple but not easy. It involves a lot of hard work. "The best thing a human being can do is to help another human being know more."
- III. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
- IV. Knowledge accumulation as an acquired, rather than natural, genius. And he'd give all the credit to the studying;.
- V. The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage ... the list goes on.
- VI. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some op-ed in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
- VII. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what happens will not agree with us. This is feedback, and how we respond to this feedback is key.

VIII. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?

- I have to do the reading.
- I have to do Thinking and mental model.
- I have to talk to competent people and understand their arguments.
- I have to think about the key variables and how they interact over time.
- I have to listen and chase down arguments that run counter to your views.
- I have to think about how you might be fooling yourself.
- I have to see the issue from multiple perspectives.
- I have to think.
- I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.

IX. If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."

X. We all are learning, modifying, or destroying ideas all the time. Rapid destruction of your ideas when the time is right is one of the most valuable qualities you can acquire. You must force yourself to consider arguments on the other side. As Rabbi Moses ben Maimon (1135–1204), commonly known as Maimonides, said: "Teach thy tongue to say I do not know, and thou shalt progress."

XI. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.

XII. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts that ran contrary to his ideas, he endeavored not only to listen but also not to rest until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

XIII. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

- Circle of Competence:

- **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve —after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time,

work to expand that circle but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

- The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.
 - The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
 - The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
 - How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge. Often they are veteran reporters who have specialized for years in a

clearly defined area. They make a serious effort to understand the complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

- Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful. Mimic and the Real Thing:
 - “There’s two kinds of snakes you come across. There’s the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it’s venomous, it can kill you in a minute. The Mexican Milk Snake can’t do anything to you; it’s an impostor.”How is it that these two look alike? It’s due to a phenomenon called Batesian Mimicry.
 - In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the “models”) were able to operate freely and relatively unmolested, there had also developed a “mimic” population of butterflies which wasn’t toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the “model” was and the more frequently they appeared in the local population, the easier it was for its “mimics” to get by! Predators simply wouldn’t take the risk of mixing up the two. If there aren’t as many “models” around or they aren’t that dangerous, the mimics have a harder time.
 - This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or “pretenders to the throne” are often very effective, very convincing “mimics” of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the “model,” the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many “future” Warren Buffett’s. For every Steve Jobs, there have been many “next” Steve Jobs’. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

XIV. The ability to destroy your ideas rapidly instead of slowly when the occasion is right is one of the most valuable things. You have to work hard on it. Ask yourself what are the arguments on the other side. It's bad to have an opinion you're proud of if you can't state the arguments for the other side better than your opponents. This is a great mental discipline.

XV. Doing the work means you can't make up your mind with a high degree of confidence right away. Doing the work forces you to challenge your beliefs because you have to argue from both sides. You become the somewhat impartial judge. What's on trial is your opinion. If you want to work with the world rather than against it, one of the major leverage points you can put effort into is how to distinguish between the people who've done the work and those who haven't. The ones who have will pass the Batesian Mimicry Test.

XVI. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.

XVII. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.

XVIII. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

XIX. We read a lot. I don't know anyone who's wise who doesn't read a lot. But that's not enough: You have to have a temperament to grab ideas and do sensible things. Most people don't grab the right ideas or don't know what to do with them.

XX. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. "Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day."

3. Step 3- Slow Down

I. Do Not Rush Thinking Process, and Do it Very Slow.

II. Do Not Rush Any Task I will do At Any Time.

III. Listen and Apply Book “The Slow Fix Solve Problems, Work Smarter, and Live Better in a World Addicted to Speed”

IV. Listen and Apply Book *In Praise Of Slowness Challenging the Cult of Speed BY Carl Honore.

- We live in a world scarce of understanding and abundant with information. We complain that we never have any free time yet we seek distraction. If work can't distract us, we distract ourselves. We crave perpetual stimulation and motion. We're so busy that our free time comes in 20 second bursts, just long enough for us to read the gist and assume we understand. If we are to synthesize learning and understanding we need time to think.
- The modern storm of bits and stimulation, relents only when we sleep. (And then only if we remember to turn off the phone.) Lost in all of this is the art of stillness. We live in a world with more information than ever and yet we understand less. We have come into the belief that the simple act of reading confers understanding. Worse, most of our reading is elementary reading, or skimming — a far cry from syntopical reading, which seems more fertile for the mind willing to do the work.
- But that's just it. We don't want, or can't find the time, to do the work that's required to hold an opinion. It's much easier to simply read the opinions of another and let them think for us.
- Understanding comes from focusing, chewing, and relentlessly ragging on a problem. It comes with false starts, dead ends, and frustration. Thinking requires time and space. It's slow. It means saying I don't know. In short, thinking is everything the modern workplace is designed to eradicate.
- We're expected to have an opinion about everything and yet our time to think is near zero. We hold more opinions than ever but have less understanding. We don't even understand ourselves. How could it be otherwise?
- As Milan Kundera wrote in his 1996 novella Slowness, “When things happen too fast, nobody can be certain about anything, about anything at all, not even about himself. “In our fast-moving modern world, it always

seems that the time-train is pulling out of the station just as we reach the platform. No matter how fast we go, no matter how cleverly we schedule, there are never enough hours in the day.”

- Carl Honore, wrote a book, In Praise of Slowness: Challenging the Cult of Speed, to explore why we’re always in such a rush, what if anything is the cure for time-sickness, and whether it’s desirable to slow down. The book is not an all-out declaration of war against speed. Speed has helped to remake our world in ways that are wonderful and liberating. Who wants to live without the Internet or jet travel? The problem is that our love of speed, our obsession with doing more and more in less and less time, has gone too far; it has turned into an addiction, a kind of idolatry. Even when speed starts to backfire, we invoke the go-faster gospel.
- When we rush, we skim the surface, and fail to make real connections with the world or other people.” Moreover we don’t make connections with ideas. We don’t synthesize. We don’t test theories over time. We don’t play with ideas.
- The implications on thinking are fascinating. We are all fast-thinkers now. We have forgotten how to look forward to things, and how to enjoy the moment when they arrive. Restaurants report that hurried diners increasingly pay the bill and order a taxi while eating dessert. Many fans leave sporting events early, no matter how close the score is, simply to steal a march on the traffic. Then there is the curse of multi-tasking. Doing two things at once seems so clever, so efficient, so modern. And yet what it often means is doing two things not very well. Like many people, I read the paper while watching TV— and find that I get less out of both. In this media-drenched, data-rich, channel-surfing, computer-gaming age, we have lost the art of doing nothing, of shutting out the background noise and distractions, of slowing down and simply being alone with our thoughts. Boredom— the word itself hardly existed 150 years ago— is a modern invention. Remove all stimulation, and we fidget, panic and look for something, anything, to do to make use of the time. When did you last see someone just gazing out the window on a train? Everyone is too busy reading the paper, playing video games, listening to iPods, working on the laptop, yammering into mobile phones. Instead of thinking deeply, or letting an idea simmer in the back of the mind, our instinct now is to reach for the

nearest sound bite. In modern warfare, correspondents in the field and pundits in the studio spew out instant analyses of events as they occur. Often their insights turn out to be wrong. But that hardly matters nowadays: in the land of speed, the man with the instant response is king. With satellite feeds and twenty-four-hour news channels, the electronic media is dominated by what one French sociologist dubbed “le fast thinker”— a person who can, without skipping a beat, summon up a glib answer to any question.

- Fast eats time. One consequence of fast is that we make poor decision after poor decision. Those decisions don’t go away never to be seen again. It’s not like we make a bad decision and we’re done with it. No, the consequences are much worse. Poor decisions eat time. They come back to haunt you. They create issue after issue. They feed into the perpetual motion machine of busyness. And in a culture where people wear busyness as a badge of honor bad decisions actually lead us to think that we’re doing more.

V. Do The Tasks Slowly, and Step By Step.

VI. The Art of Slowing down and Do Not Rush Anything.

- The Art of Stillness is a persuasively argued case for the pleasures of slowing down and being in one place. Today we’re going faster and faster in search of contentment and meaning. This is largely a recipe for ensuring we will never be happy. We have the sense, too often, of running at top speed and never being able to catch up.
- Too many of us see going nowhere as turning away from something rather than turning towards something.
- Going nowhere isn’t about turning your back on the world; it’s about stepping away now and then so that you can see the world more clearly and love it more deeply. “There is nothing either good or bad, but thinking makes it so.”
- The idea behind choosing to sit still long enough to learn about yourself is simple and has been around for ages. Marcus Aurelius and Epictetus reminded us many millennia ago that it’s how we respond to our experiences, not the experiences themselves, which shape us.

- The greatest weapon against stress is our ability to choose one thought over another. Part of making better decisions is making time to think. Something that few of us are able to do.
- “Our creations come not when we’re out in the world, gathering impressions, but when we’re sitting still, turning those impressions into sentences.

4. Step 4- Do not Multitask.

- I. Of course you can do more than one thing at once. The catch is you can’t do more more than one thing at once that requires concentration. You can walk and chew gum, but you can’t write an email and a report at the same time. When you’re doing two things at once that are cognitively demanding, what you’re really doing is switching back and forth very quickly from one task to another.
- II. There is a mental cost—called a switching cost—to all of this multitasking. But that’s not all it makes deep thinking impossible.
- III. I think people that multitask pay a huge price. They think they’re being extra productive, and I think they’re (out of their mind). I use the metaphor of the one-legged man in the ass-kicking contest. I think when you multi-task so much, you don’t have time to think about anything deeply. You’re giving the world an advantage you shouldn’t do. Practically everybody is drifting into that mistake. Concentrating hard on something that is important is. I can’t succeed at all without doing it. I did not succeed in life by intelligence. I succeeded because I have a long attention span.
- IV. It sounds counter-intuitive but if you want to increase discretionary time and reduce stress you need to schedule time to think. The tiny fragments of time many of us find ourselves with have a negative effect on our ability to think deeply about a problem. Furthermore they impede our ability to learn — we stay at a surface level and never move into a deep understanding. Deresiewicz warns: “You simply cannot (think) in bursts of 20 seconds at a time, constantly interrupted by Facebook messages or Twitter tweets, or fiddling with your iPod, or watching something on YouTube.”
- V. The opposite approach is to focus on a problem or subject and try to achieve a deep fluency. How many of us, however, have time? We don’t do the work required to have an opinion. Instead we operate with surface knowledge. We tackle problems with the first thought that comes to mind. Because we make a

poor initial decision, we spend countless hours attempting to correct it. No wonder we have no time to think. We're not heeding the advice of Joseph Tussman and letting the world do the work for us.

VI. Listen and Apply The Following Books:

- **The Multitasking Mind By Dario Saliveci**

5. Step 5-What is Thinking/

I. Thinking Rate

- You can't force yourself to think faster. If you try, you're likely to end up making much worse decisions. Here's how to improve the actual quality of your decisions instead of chasing hacks to speed them up.
- When the product of your job is your decisions, you might find yourself wanting to be able to make more decisions more quickly so you can be more productive overall.
- Chasing speed is a flawed approach. Because decisions—at least good ones—don't come out of thin air. They're supported by a lot of thinking.

II. Beyond The Hurry Culture

- Everyone is trying to work faster at all times, and they pressure everyone around them to work faster, too.
- All of these things increase pressure in the work environment and repeatedly reinforce the "hurry up!" message. They make managers feel like they're moving things along faster. That way if work isn't getting done, it's not their fault. But, DeMarco writes, they don't lead to meaningful changes in behavior that make the whole organization more productive. Speeding up often results in poor decisions that create future problems.
- The reason more pressure doesn't mean better productivity is that the rate at which we think is fixed. We can't force ourselves to start making faster decisions right now just because we're faced with an unrealistic deadline. DeMarco writes, *"Think rate is fixed. No matter what you do, no matter how hard you try, you can't pick up the pace of thinking."*

III. Elements of Effective Thinking

- **Understand Deeply.** Don't face complex issues head-on; first understand simple ideas deeply. Clear the clutter and expose what is really important. Be brutally honest about what you know and don't know. Then see what's missing, identify the gaps, and fill them in. Let go of bias, prejudice, and preconceived notions. There are degrees to understanding (it's not just a yes-or-no proposition) and you can always heighten yours. Rock-solid understanding is the foundation for success.
- **Make Mistakes.** Fail to succeed. Intentionally get it wrong to inevitably get it even more right. Mistakes are great teachers — they highlight unforeseen opportunities and holes in your understanding. They also show you which way to turn next, and they ignite your imagination.
- **Raise Questions.** Constantly create questions to clarify and extend your understanding. What's the real question? Working on the wrong questions can waste a lifetime. Ideas are in the air — the right questions will bring them out and help you see connections that otherwise would have been invisible.
- **Follow the Flow of Ideas.** Look back to see where ideas came from and then look ahead to discover where those ideas may lead. A new idea is a beginning, not an end. Ideas are rare— milk them. Following the consequences of small ideas can result in big payoffs. These are the four basic building blocks for effective thinking. The fifth is Change.
- **Change.** The unchanging element is change— by mastering the first four elements, you can change the way you think and learn. You can always improve, grow, and extract more out of your education, yourself, and the way you live your life. Change is the universal constant that allows you to get the most out of living and learning.

6. Step 6-Collect As Many mental models as Possible from diverse domains and academic disciplines That I think is suitable for my situation or Information provided by the Text, Book, Speech etc. Research a broad range of industries to identify mental models that can be integrated and Most Suitable into area of work or focus. In identifying the Great Mental Models we have to look for elementary principles, the ideas from multiple disciplines that form a time tested foundation, these mental models would be from Elementary Mental Models to most Advanced Mental Models. It may seem counterintuitive, to work on developing knowledge that is available to everyone, but the universe works in the same way no matter where you are in it or how you think the universe should be working. What you need is to understand the principles, so that when the details change you are still I to identify what is really going on. Listen and Follow Every Book on Each Mental models.

A. General Mental Models For Thinking.

I. The Great Mental Models Volume 1 By Fs Blog.

- The Map is Not The Territory.
- Circle of Competence.
- The first Principles Thinking.
- Though Experiment.
- Second Order Thinking.
- Probabilistic Thinking.
- Inversion.
- Occam's Razor.
- Hanlon's Razor.
- Supporting Ideas.
- Falsifiability.
- Necessity and Sufficiency.
- Causation vs Correlation.
- The 48 Laws of Power By Robert Greene
- How to Think By John Dewey

II. The Great Mental Models Volume 2 By Fs Blog.

- Physics.
 - Relativity.
 - Reciprocity.

- Thermodynamics.
- Inertia.
- Friction and Viscosity.
- Velocity
- Leverage.

- Chemistry.
 - Activation Energy.
 - Catalysts.
 - Alloying,

- Biology.
 - Evolution Part One: Natural Selection and Extinction.
 - Evolution Part two: Adaptation Rate and The Red Queen Effect.
 - Supporting Idea: Competition.
 - Ecosystem.
 - Niche.
 - Self Preservation.
 - Replication.
 - Cooperation.
 - Supporting Idea: Dunbar's Number.
 - Hierarchical Organisation.
 - Incentives.
 - Tendency to Minimize energy Output.

III. The Great Mental Models Volume 3 By Fs Blog.

- Systems.
 - Feedback Loops.
 - Equilibrium.
 - Bottlenecks.
 - Scale.
 - Margin of Safety.
 - Churn.
 - Algorithms.

- Supporting Idea: Complex Adaptive Systems.
- Critical mass.
- Emergence.
- Supporting Idea: Chaos Dynamics.
- Irreducibility.
- Law of Diminishing Returns.
- Mathematics.
 - Supporting Idea: Distribution.
 - Compounding.
 - Supporting Idea; Network Effect.
 - Sampling.
 - Randomness.
 - Supporting idea: Pareto Principle.
 - Regression to the mean.
 - Multiplying by ZERO.
 - Equivalence.
 - Supporting idea: order of Magnitude.
 - Surface Area.
 - Global and local Maxima.

IV. The Great Mental Models By Tommy Tedford.

- First Principles Mental model.
- Classical Condition.
- Cognitive Biases.
- Circle Of Competence Mental Model.
- Eisenhower Matrix.

V. 100 Mental Models- Be Rational by Wisdom Theory.

- Philosophy.
 - Meaning Of Life.
 - Stoicism.
 - Cave of plato.
 - Golden Rule.
 - Constructivism.

- **Maths.**
 - Algebra.
 - Permutations and combinations.
 - Algorithms.
 - Scale.
 - Compound interest.
 - Inflection point.

- **Physics.**
 - Scientific Method.
 - Breakpoint.
 - Critical mass.
 - Reciprocity.
 - Velocity.
 - Relativity.
 - Leverage.
 - Newton's Laws of Motion.
 - Chaos Theory.
 - Complex Adaptive Systems.
 - Activation Energy.
 - Laws of Thermodynamics.
 - Heisenberg Uncertainty Principle.

- **Statistics.**
 - Probabilistic thinking.
 - Bayes Theorem.
 - Power Law.
 - Regression to the Mean.
 - Game Theory.
 - Correlation and Causation.
 - Standard Deviation.
 - Law of large numbers.
 - Inversion.
 - Fragility / Robustness / Antifragility.
 - Black Swan.

- **Engineering.**
 - **Redundancy: Margin of safety.**
 - **Backup system model.**
 - **Breakpoint.**
 - **Quality control.**
 - **Feedback loops.**

- **Chemistry.**
 - **Atoms, Molecules, and Ions.**
 - **The Chemical Bond.**
 - **Molecular Shape and Geometry.**
 - **The Kinetic Theory.**
 - **The Chemical Reaction.**
 - **Autocatalyst.**

- **Biology.**
 - **Modern Darwinian Synthesis.**
 - **Incentives.**
 - **Scarcity.**
 - **Cooperation.**

7. **Step 7-Getting familiar:** At this starting point, users decide if they can use an existing mental model (maybe one used for another similar product) or if they need to start from scratch. The existing mental model may be void of useful knowledge or worse, contain the wrong knowledge. The core components missing at this stage include an understanding of the language the product uses and the actionable steps needed to complete core tasks.
8. **Step 8-Apply simple criteria to which mental models you use.** When selecting mental models to include into your own latticework, consider whether they support you to better understand yourself and/or the world around you, so you might better effective and impactful action. Also Mental models do two things: they help you assess how things work and they help you make better decisions. Ask some Questions:
 - I. How long has this model been around? As a general rule, mental models which have been around for a long time (such as Occam's razor) will have been subjected to a great deal of scrutiny. Time is an excellent curator, trimming away inefficient ideas. A mental model which is new may not be particularly refined or versatile. Many of our mental models originate from Ancient Greece and Rome, meaning they have to be functional to have survived this long.
 - II. Is it a representation of reality? In other words, does it reflect the real world? Or is it based on abstractions?
 - III. Does this model apply to multiple areas? The more elastic a model is, the more valuable it is to learn about. (Of course, be careful not to apply the model where it doesn't belong. Mind Feynman: "You must not fool yourself, and you're the easiest person to fool.")
 - IV. How did this model originate? Many mental models arise from scientific or mathematical concepts. The more fundamental the domain, the more likely the model is to be true and lasting.
 - V. Is it based on first principles? A first principle is a foundational concept which cannot be deduced from any other concept and must be known.
 - VI. Does it require infinite regress? Infinite regress refers to something which is justified by principles, which themselves require justification by other principles. A model based on infinite regress is likely to

required extensive knowledge of a particular topic, and have minimal real-world application.

9. **Step 9- *Becoming proficient*:** Users begin to understand the language of the situation or text, especially if this language uses technical or unfamiliar vernacular. Understanding terminology and use of product language is one of the first building blocks that form the foundation of the model. This is also when users start to understand the step-by-step procedures required to perform basic operations to get some desired outcome. Here, they are usually learning the bread-and-butter operations of the product so they can receive enough value to motivate them to keep using it. Later, they will be able to build on this knowledge.
10. **Step 10- Make connections between mental models.** We need to know full context and not isolated facts. Rather than holding siloed mental models in your mind, consider how they interact, connect and complement one another.
11. **Step 11-Think, what light the mental model can bring on the situation, idea, text , speech etc.** Do I see the situation, idea, text, speech etc, in the new way? What new way can I see the situation? Does This Makes easier to make a decision in my life?
12. **Step 12- Think very carefully, if each chosen Mental model applicable to situation, idea, text, speech etc.**
13. **Step 13-Use the Chosen Mental Models tool.** The canvas, below, will help you to identify high-value areas where new mental models can make the biggest impact on your work and life. It also provides a simple framework to begin to embed using your chosen models.
14. **Step 14-*Mastering*:** Users build on the core step-by-step tasks they already know, expanding their knowledge to more complex or niche capabilities. If they make it this far they most likely have an accurate understanding of most or all of the language the product uses.
15. **Step 15-Regularly reassess their priorities without fear of changing them.** They don't fall prey to inertia.
16. **Step 16-Be biased toward taking action—not lazily deferring.** If they encounter a mental model they value, they make sure they use it.
17. **Step 17-Be always looking to prove yourselves wrong.** Ego should not get in the way of mental models.

18. Step 18-Accepting that all models are wrong in certain instances is not a license to ignore the facts. As a society, we should search for better answers, look for evidence, and strive to increase the accuracy of our knowledge.

- I. That's not to say all lenses (or models) apply to all problems. They don't. And it's not to say that having more lenses (or models) will be a advantage in all problems. It won't. This is why learning and applying the Great Mental Models is a process that takes some work. But the truth is, most problems are multidimensional, and thus having more lenses often offers significant help with the problems we are facing.**
- II. The more you use them, the more you will be able to build the knowledge of indicators that can trigger the use of the most appropriate model. Using and failing, as long as you acknowledge, reflect, and learn from it, is also how you build your repertoire. You need to be deliberate about choosing the models you will use in a situation. As you use them, a great practice is to record and reflect. That way you can get better at both choosing models and applying them. Take the time to notice how you applied them, what the process was like, and what the results were. Over time you will develop your knowledge of which situations are best tackled through which models. Don't give up on a model if it doesn't help you right away. Learn more about it, and try to figure out exactly why it didn't work. It may be that you have to improve your understanding. Or there were aspects of the situation that you did not consider. Or that your focus was on the wrong variable.**

- 19. Step 19-After all Analysis, decide what models are the most suitable after all to apply.**
- 20. Step 20-Apply The Mental Model in Real Life or Reality, and let the world do the work for You.**

Step 63 - CrossDisciplinary Thinking

1. **Step 1 Define CrossDisciplinary Thinking.** Crossdisciplinary thinking applies to several types of cross border interactions, looking at one discipline from an other's viewpoint. You will be working together to move knowledge from one discipline to the other. For example, views from political science are being used in fictional literature to understand political dispute. As part of the current university, cross-disciplinarity has a long background, particularly among disciplines that share borders or those with a shared focus. Physics and astronomy disciplines demonstrate this background. Physics studies a law that determines the universe; these laws extend to non-Earthly contexts (to the best of modern knowledge). Physics and astronomy programs are therefore usually located in the same academic department, providing for cross-disciplinary interaction. Crossdisciplinary working views one discipline from the frame of reference of another. It's like lots of different ingredients on a plate, but without chopping them up and mixing them. Let's review the process that Pinker has laid out, one that we might think about emulating as we examine the causes of complex phenomena in human systems:

- III. We observe an interesting phenomenon in need of explanation, one we feel capable of exploring.
- IV. We propose and examine competing hypotheses that would explain the phenomena (set up in a falsifiable way, in harmony with the divide between science and pseudoscience laid out for us by the great Karl Popper).
- V. We examine a cross-section of: Empirical data relating to the phenomena; sensible qualitative inference (from multiple fields/disciplines, the more fundamental the better), and finally; "Demonstrable" aspects of nature we are nearly certain about, arising from controlled experiment or other rigorous sources of knowledge ranging from engineering to biology to cognitive neuroscience.
- VI. Listen and Apply The Following Books:
 - **How we can Assess the Level of Interdisciplinarity and Transdisciplinarity of Academic Institutions? By Mahmood Ramezanzade**

- **Detection of Distributed Denial of Service (DDoS) Attacks in IOT Based Monitoring System of Banking Sector Using Machine Learning Models By Muhsmmsf Shafiq**

2. Step 2-Do Work Required to Have an Opinion on Any Topic and Anything.

- I. Most people go through life not really getting any smarter. Why? They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
- II. You can acquire knowledge if you want it. In fact, there is a simple formula, which if followed is almost certain to make you smarter over time. Simple but not easy. It involves a lot of hard work. "The best thing a human being can do is to help another human being know more."
- III. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
- IV. Knowledge accumulation as an acquired, rather than natural, genius. And he'd give all the credit to the studying;.
- V. The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage ... the list goes on.
- VI. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some op-ed in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
- VII. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what happens will not agree with us. This is feedback, and how we respond to this feedback is key.

VIII. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?

- I have to do the reading.
- I have to do Thinking and mental model.
- I have to talk to competent people and understand their arguments.
- I have to think about the key variables and how they interact over time.
- I have to listen and chase down arguments that run counter to your views.
- I have to think about how you might be fooling yourself.
- I have to see the issue from multiple perspectives.
- I have to think.
- I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.

IX. If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."

X. We all are learning, modifying, or destroying ideas all the time. Rapid destruction of your ideas when the time is right is one of the most valuable qualities you can acquire. You must force yourself to consider arguments on the other side. As Rabbi Moses ben Maimon (1135–1204), commonly known as Maimonides, said: "Teach thy tongue to say I do not know, and thou shalt progress."

XI. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.

XII. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts that ran contrary to his ideas, he endeavored not only to listen but also not to rest until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

XIII. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

- Circle of Competence:

- **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve —after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time,

work to expand that circle but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

- The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.
 - The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
 - The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
 - How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge. Often they are veteran reporters who have specialized for years in a

clearly defined area. They make a serious effort to understand the complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

- Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful. Mimic and the Real Thing:
 - “There’s two kinds of snakes you come across. There’s the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it’s venomous, it can kill you in a minute. The Mexican Milk Snake can’t do anything to you; it’s an impostor.”How is it that these two look alike? It’s due to a phenomenon called Batesian Mimicry.
 - In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the “models”) were able to operate freely and relatively unmolested, there had also developed a “mimic” population of butterflies which wasn’t toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the “model” was and the more frequently they appeared in the local population, the easier it was for its “mimics” to get by! Predators simply wouldn’t take the risk of mixing up the two. If there aren’t as many “models” around or they aren’t that dangerous, the mimics have a harder time.
 - This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or “pretenders to the throne” are often very effective, very convincing “mimics” of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the “model,” the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many “future” Warren Buffett’s. For every Steve Jobs, there have been many “next” Steve Jobs’. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

XIV. The ability to destroy your ideas rapidly instead of slowly when the occasion is right is one of the most valuable things. You have to work hard on it. Ask yourself what are the arguments on the other side. It's bad to have an opinion you're proud of if you can't state the arguments for the other side better than your opponents. This is a great mental discipline.

XV. Doing the work means you can't make up your mind with a high degree of confidence right away. Doing the work forces you to challenge your beliefs because you have to argue from both sides. You become the somewhat impartial judge. What's on trial is your opinion. If you want to work with the world rather than against it, one of the major leverage points you can put effort into is how to distinguish between the people who've done the work and those who haven't. The ones who have will pass the Batesian Mimicry Test.

XVI. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.

XVII. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.

XVIII. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

XIX. We read a lot. I don't know anyone who's wise who doesn't read a lot. But that's not enough: You have to have a temperament to grab ideas and do sensible things. Most people don't grab the right ideas or don't know what to do with them.

XX. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. "Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day."

3. Step 3- Slow Down

I. Do Not Rush Thinking Process, and Do it Very Slow.

II. Do Not Rush Any Task I will do At Any Time.

III. Listen and Apply Book “The Slow Fix Solve Problems, Work Smarter, and Live Better in a World Addicted to Speed”

IV. Listen and Apply Book *In Praise Of Slowness Challenging the Cult of Speed BY Carl Honore.

- We live in a world scarce of understanding and abundant with information. We complain that we never have any free time yet we seek distraction. If work can't distract us, we distract ourselves. We crave perpetual stimulation and motion. We're so busy that our free time comes in 20 second bursts, just long enough for us to read the gist and assume we understand. If we are to synthesize learning and understanding we need time to think.
- The modern storm of bits and stimulation, relents only when we sleep. (And then only if we remember to turn off the phone.) Lost in all of this is the art of stillness. We live in a world with more information than ever and yet we understand less. We have come into the belief that the simple act of reading confers understanding. Worse, most of our reading is elementary reading, or skimming — a far cry from syntopical reading, which seems more fertile for the mind willing to do the work.
- But that's just it. We don't want, or can't find the time, to do the work that's required to hold an opinion. It's much easier to simply read the opinions of another and let them think for us.
- Understanding comes from focusing, chewing, and relentlessly ragging on a problem. It comes with false starts, dead ends, and frustration. Thinking requires time and space. It's slow. It means saying I don't know. In short, thinking is everything the modern workplace is designed to eradicate.
- We're expected to have an opinion about everything and yet our time to think is near zero. We hold more opinions than ever but have less understanding. We don't even understand ourselves. How could it be otherwise?
- As Milan Kundera wrote in his 1996 novella Slowness, “When things happen too fast, nobody can be certain about anything, about anything at all, not even about himself. “In our fast-moving modern world, it always

seems that the time-train is pulling out of the station just as we reach the platform. No matter how fast we go, no matter how cleverly we schedule, there are never enough hours in the day.”

- Carl Honore, wrote a book, In Praise of Slowness: Challenging the Cult of Speed, to explore why we’re always in such a rush, what if anything is the cure for time-sickness, and whether it’s desirable to slow down. The book is not an all-out declaration of war against speed. Speed has helped to remake our world in ways that are wonderful and liberating. Who wants to live without the Internet or jet travel? The problem is that our love of speed, our obsession with doing more and more in less and less time, has gone too far; it has turned into an addiction, a kind of idolatry. Even when speed starts to backfire, we invoke the go-faster gospel.
- When we rush, we skim the surface, and fail to make real connections with the world or other people.” Moreover we don’t make connections with ideas. We don’t synthesize. We don’t test theories over time. We don’t play with ideas.
- The implications on thinking are fascinating. We are all fast-thinkers now. We have forgotten how to look forward to things, and how to enjoy the moment when they arrive. Restaurants report that hurried diners increasingly pay the bill and order a taxi while eating dessert. Many fans leave sporting events early, no matter how close the score is, simply to steal a march on the traffic. Then there is the curse of multi-tasking. Doing two things at once seems so clever, so efficient, so modern. And yet what it often means is doing two things not very well. Like many people, I read the paper while watching TV— and find that I get less out of both. In this media-drenched, data-rich, channel-surfing, computer-gaming age, we have lost the art of doing nothing, of shutting out the background noise and distractions, of slowing down and simply being alone with our thoughts. Boredom— the word itself hardly existed 150 years ago— is a modern invention. Remove all stimulation, and we fidget, panic and look for something, anything, to do to make use of the time. When did you last see someone just gazing out the window on a train? Everyone is too busy reading the paper, playing video games, listening to iPods, working on the laptop, yammering into mobile phones. Instead of thinking deeply, or letting an idea simmer in the back of the mind, our instinct now is to reach for the

nearest sound bite. In modern warfare, correspondents in the field and pundits in the studio spew out instant analyses of events as they occur. Often their insights turn out to be wrong. But that hardly matters nowadays: in the land of speed, the man with the instant response is king. With satellite feeds and twenty-four-hour news channels, the electronic media is dominated by what one French sociologist dubbed “le fast thinker”— a person who can, without skipping a beat, summon up a glib answer to any question.

- Fast eats time. One consequence of fast is that we make poor decision after poor decision. Those decisions don’t go away never to be seen again. It’s not like we make a bad decision and we’re done with it. No, the consequences are much worse. Poor decisions eat time. They come back to haunt you. They create issue after issue. They feed into the perpetual motion machine of busyness. And in a culture where people wear busyness as a badge of honor bad decisions actually lead us to think that we’re doing more.

V. Do The Tasks Slowly, and Step By Step.

VI. The Art of Slowing down and Do Not Rush Anything.

- The Art of Stillness is a persuasively argued case for the pleasures of slowing down and being in one place. Today we’re going faster and faster in search of contentment and meaning. This is largely a recipe for ensuring we will never be happy. We have the sense, too often, of running at top speed and never being able to catch up.
- Too many of us see going nowhere as turning away from something rather than turning towards something.
- Going nowhere isn’t about turning your back on the world; it’s about stepping away now and then so that you can see the world more clearly and love it more deeply. “There is nothing either good or bad, but thinking makes it so.”
- The idea behind choosing to sit still long enough to learn about yourself is simple and has been around for ages. Marcus Aurelius and Epictetus reminded us many millennia ago that it’s how we respond to our experiences, not the experiences themselves, which shape us.

- The greatest weapon against stress is our ability to choose one thought over another. Part of making better decisions is making time to think. Something that few of us are able to do.
- “Our creations come not when we’re out in the world, gathering impressions, but when we’re sitting still, turning those impressions into sentences.

4. Step 4- Do not Multitask.

- I. Of course you can do more than one thing at once. The catch is you can’t do more more than one thing at once that requires concentration. You can walk and chew gum, but you can’t write an email and a report at the same time. When you’re doing two things at once that are cognitively demanding, what you’re really doing is switching back and forth very quickly from one task to another.
- II. There is a mental cost—called a switching cost—to all of this multitasking. But that’s not all it makes deep thinking impossible.
- III. I think people that multitask pay a huge price. They think they’re being extra productive, and I think they’re (out of their mind). I use the metaphor of the one-legged man in the ass-kicking contest. I think when you multi-task so much, you don’t have time to think about anything deeply. You’re giving the world an advantage you shouldn’t do. Practically everybody is drifting into that mistake. Concentrating hard on something that is important is. I can’t succeed at all without doing it. I did not succeed in life by intelligence. I succeeded because I have a long attention span.
- IV. It sounds counter-intuitive but if you want to increase discretionary time and reduce stress you need to schedule time to think. The tiny fragments of time many of us find ourselves with have a negative effect on our ability to think deeply about a problem. Furthermore they impede our ability to learn — we stay at a surface level and never move into a deep understanding. Deresiewicz warns: “You simply cannot (think) in bursts of 20 seconds at a time, constantly interrupted by Facebook messages or Twitter tweets, or fiddling with your iPod, or watching something on YouTube.”
- V. The opposite approach is to focus on a problem or subject and try to achieve a deep fluency. How many of us, however, have time? We don’t do the work required to have an opinion. Instead we operate with surface knowledge. We tackle problems with the first thought that comes to mind. Because we make a

poor initial decision, we spend countless hours attempting to correct it. No wonder we have no time to think. We're not heeding the advice of Joseph Tussman and letting the world do the work for us.

VI. Listen and Apply The Following Books:

- **The Multitasking Mind By Dario Saliveci**

5. Step 5-What is Thinking/

I. Thinking Rate

- You can't force yourself to think faster. If you try, you're likely to end up making much worse decisions. Here's how to improve the actual quality of your decisions instead of chasing hacks to speed them up.
- When the product of your job is your decisions, you might find yourself wanting to be able to make more decisions more quickly so you can be more productive overall.
- Chasing speed is a flawed approach. Because decisions—at least good ones—don't come out of thin air. They're supported by a lot of thinking.

II. Beyond The Hurry Culture

- Everyone is trying to work faster at all times, and they pressure everyone around them to work faster, too.
- All of these things increase pressure in the work environment and repeatedly reinforce the "hurry up!" message. They make managers feel like they're moving things along faster. That way if work isn't getting done, it's not their fault. But, DeMarco writes, they don't lead to meaningful changes in behavior that make the whole organization more productive. Speeding up often results in poor decisions that create future problems.
- The reason more pressure doesn't mean better productivity is that the rate at which we think is fixed. We can't force ourselves to start making faster decisions right now just because we're faced with an unrealistic deadline. DeMarco writes, *"Think rate is fixed. No matter what you do, no matter how hard you try, you can't pick up the pace of thinking."*

III. Elements of Effective Thinking

- **Understand Deeply.** Don't face complex issues head-on; first understand simple ideas deeply. Clear the clutter and expose what is really important. Be brutally honest about what you know and don't know. Then see what's missing, identify the gaps, and fill them in. Let go of bias, prejudice, and preconceived notions. There are degrees to understanding (it's not just a yes-or-no proposition) and you can always heighten yours. Rock-solid understanding is the foundation for success.
- **Make Mistakes.** Fail to succeed. Intentionally get it wrong to inevitably get it even more right. Mistakes are great teachers — they highlight unforeseen opportunities and holes in your understanding. They also show you which way to turn next, and they ignite your imagination.
- **Raise Questions.** Constantly create questions to clarify and extend your understanding. What's the real question? Working on the wrong questions can waste a lifetime. Ideas are in the air — the right questions will bring them out and help you see connections that otherwise would have been invisible.
- **Follow the Flow of Ideas.** Look back to see where ideas came from and then look ahead to discover where those ideas may lead. A new idea is a beginning, not an end. Ideas are rare— milk them. Following the consequences of small ideas can result in big payoffs. These are the four basic building blocks for effective thinking. The fifth is Change.
- **Change.** The unchanging element is change— by mastering the first four elements, you can change the way you think and learn. You can always improve, grow, and extract more out of your education, yourself, and the way you live your life. Change is the universal constant that allows you to get the most out of living and learning.

6. Step 6-Collect As Many mental models as Possible from diverse domains and academic disciplines That I think is suitable for my situation or Information provided by the Text, Book, Speech etc. Research a broad range of industries to identify mental models that can be integrated and Most Suitable into area of work or focus. In identifying the Great Mental Models we have to look for elementary principles, the ideas from multiple disciplines that form a time tested foundation, these mental models would be from Elementary Mental Models to most Advanced Mental Models. It may seem counterintuitive, to work on developing knowledge that is available to everyone, but the universe works in the same way no matter where you are in it or how you think the universe should be working. What you need is to understand the principles, so that when the details change you are still able to identify what is really going on. Listen and Follow Every Book on Each Mental models.

A. General Mental Models For Thinking.

I. The Great Mental Models Volume 1 By Fs Blog.

- The Map is Not The Territory.
- Circle of Competence.
- The first Principles Thinking.
- Though Experiment.
- Second Order Thinking.

- 7. Step 7-Getting familiar:** At this starting point, users decide if they can use an existing mental model (maybe one used for another similar product) or if they need to start from scratch. The existing mental model may be void of useful knowledge or worse, contain the wrong knowledge. The core components missing at this stage include an understanding of the language the product uses and the actionable steps needed to complete core tasks.
- 8. Step 8-Apply simple criteria to which mental models you use.** When selecting mental models to include into your own latticework, consider whether they support you to better understand yourself and/or the world around you, so you might better effective and impactful action. Also Mental models do two things: they help you assess how things work and they help you make better decisions. Ask some Questions:
 - I. How long has this model been around?** As a general rule, mental models which have been around for a long time (such as Occam's razor) will have been subjected to a great deal of scrutiny. Time is an excellent curator, trimming away inefficient ideas. A mental model which is new may not be particularly refined or versatile. Many of our mental models originate from Ancient Greece and Rome, meaning they have to be functional to have survived this long.
 - II. Is it a representation of reality?** In other words, does it reflect the real world? Or is it based on abstractions?
 - III. Does this model apply to multiple areas?** The more elastic a model is, the more valuable it is to learn about. (Of course, be careful not to apply the model where it doesn't belong. Mind Feynman: "You must not fool yourself, and you're the easiest person to fool.")
 - IV. How did this model originate?** Many mental models arise from scientific or mathematical concepts. The more fundamental the domain, the more likely the model is to be true and lasting.
 - V. Is it based on first principles?** A first principle is a foundational concept which cannot be deduced from any other concept and must be known.
 - VI. Does it require infinite regress?** Infinite regress refers to something which is justified by principles, which themselves require justification by other principles. A model based on infinite regress is likely to

required extensive knowledge of a particular topic, and have minimal real-world application.

9. **Step 9- *Becoming proficient*:** Users begin to understand the language of the situation or text, especially if this language uses technical or unfamiliar vernacular. Understanding terminology and use of product language is one of the first building blocks that form the foundation of the model. This is also when users start to understand the step-by-step procedures required to perform basic operations to get some desired outcome. Here, they are usually learning the bread-and-butter operations of the product so they can receive enough value to motivate them to keep using it. Later, they will be able to build on this knowledge.
10. **Step 10- Make connections between mental models.** We need to know full context and not isolated facts. Rather than holding siloed mental models in your mind, consider how they interact, connect and complement one another.
11. **Step 11-Think, what light the mental model can bring on the situation, idea, text , speech etc.** Do I see the situation, idea, text, speech etc, in the new way? What new way can I see the situation? Does This Makes easier to make a decision in my life?
12. **Step 12- Think very carefully, if each chosen Mental model applicable to situation, idea, text, speech etc.**
13. **Step 13-Use the Chosen Mental Models tool.** The canvas, below, will help you to identify high-value areas where new mental models can make the biggest impact on your work and life. It also provides a simple framework to begin to embed using your chosen models.
14. **Step 14-*Mastering*:** Users build on the core step-by-step tasks they already know, expanding their knowledge to more complex or niche capabilities. If they make it this far they most likely have an accurate understanding of most or all of the language the product uses.
15. **Step 15-Regularly reassess their priorities without fear of changing them.** They don't fall prey to inertia.
16. **Step 16-Be biased toward taking action—not lazily deferring.** If they encounter a mental model they value, they make sure they use it.
17. **Step 17-Be always looking to prove yourselves wrong.** Ego should not get in the way of mental models.

18. Step 18-Accepting that all models are wrong in certain instances is not a license to ignore the facts. As a society, we should search for better answers, look for evidence, and strive to increase the accuracy of our knowledge.

- I. That's not to say all lenses (or models) apply to all problems. They don't. And it's not to say that having more lenses (or models) will be a advantage in all problems. It won't. This is why learning and applying the Great Mental Models is a process that takes some work. But the truth is, most problems are multidimensional, and thus having more lenses often offers significant help with the problems we are facing.**
- II. The more you use them, the more you will be able to build the knowledge of indicators that can trigger the use of the most appropriate model. Using and failing, as long as you acknowledge, reflect, and learn from it, is also how you build your repertoire. You need to be deliberate about choosing the models you will use in a situation. As you use them, a great practice is to record and reflect. That way you can get better at both choosing models and applying them. Take the time to notice how you applied them, what the process was like, and what the results were. Over time you will develop your knowledge of which situations are best tackled through which models. Don't give up on a model if it doesn't help you right away. Learn more about it, and try to figure out exactly why it didn't work. It may be that you have to improve your understanding. Or there were aspects of the situation that you did not consider. Or that your focus was on the wrong variable.**

- 19. Step 19-After all Analysis, decide what models are the most suitable after all to apply.**
- 20. Step 20-Apply The Mental Model in Real Life or Reality, and let the world do the work for You.**

Step 64-Interdisciplinary Thinking

1. **Step 1 Define Interdisciplinary Thinking.** "Interdisciplinary" comes from the process of merging and integrating different disciplines together with their methodologies and presumptions. It includes crossing the formal borders between sciences and combining their methods in favor of a common purpose. "Methodologies and assumptions belonging to different disciplines are connected and modified in order to adapt to the needs of the research, creating new tools which allow for the investigation of difficult subjects that surpass the possibilities of a single discipline. In the field of architecture, for instance, complex topics such as SDGs, urban transitional, sustainability, and design imply various approaches that combine chemistry, drafting for design, engineering design, fundamentals of physics, architectural illumination and electrical systems. Interdisciplinarity may be regarded as a step up from multidisciplinary. Interdisciplinary studies focus on addressing specific 'real world' system problems and, as a result, the research process forces participants (from a variety of unrelated disciplines) to cross boundaries to create new knowledge. Essentially the major difference from multidisciplinary lies in the *level of integration and cooperation* as these projects seek to bridge disciplinary viewpoints and potentially enable the examination of existing accumulated knowledge from the perspective of a neighboring discipline. Huutoniemi *et al.* provide a relatively comprehensive typology of interdisciplinarity along with specific indicators for research teams to grasp on to. At the same time, Schmidt outlines the importance of a basic literacy in the philosophy of science related to doing such work as well as the kinds of interdisciplinarity. The necessity of bridging disciplinary viewpoints generally (as with transdisciplinarity) stems from the need to address complex "problems that involve an interface of human and natural systems" and, as such, the integration of natural and social scientists is standard practice for interdisciplinary research. This approach involves bringing people and ideas together from different disciplines to jointly frame a problem, agree on a methodological approach, and analyze data. Thus interdisciplinary research requires a much more collaborative approach to problem formulation and methodological development than multidisciplinary research. Interdisciplinary

working starts to take a new form, integrating knowledge and methods from different disciplines and synthesising into a new whole. It's like a stew: the original ingredients are still partly distinguishable, but the overall is a blended pot of mixed flavours. Let's review the process that Pinker has laid out, one that we might think about emulating as we examine the causes of complex phenomena in human systems:

- III. We observe an interesting phenomenon in need of explanation, one we feel capable of exploring.
- IV. We propose and examine competing hypotheses that would explain the phenomena (set up in a falsifiable way, in harmony with the divide between science and pseudoscience laid out for us by the great Karl Popper).
- V. We examine a cross-section of: Empirical data relating to the phenomena; sensible qualitative inference (from multiple fields/disciplines, the more fundamental the better), and finally; "Demonstrable" aspects of nature we are nearly certain about, arising from controlled experiment or other rigorous sources of knowledge ranging from engineering to biology to cognitive neuroscience.
- VI. Listen and Apply The Following Books:
 - **How we can Assess the Level of Interdisciplinarity and Transdisciplinarity of Academic Institutions? By Mahmood Ramezanzade**
 - **Detection of Distributed Denial of Service (DDoS) Attacks in IOT Based Monitoring System of Banking Sector Using Machine Learning Models By Muhsmmsf Shafiq**

2. Step 2-Do Work Required to Have an Opinion on Any Topic and Anything.

- I. Most people go through life not really getting any smarter. Why? They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
- II. You can acquire knowledge if you want it. In fact, there is a simple formula, which if followed is almost certain to make you smarter over time. Simple but not easy. It involves a lot of hard work. "The best thing a human being can do is to help another human being know more."
- III. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
- IV. Knowledge accumulation as an acquired, rather than natural, genius. And he'd give all the credit to the studying;.
- V. The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage ... the list goes on.
- VI. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some op-ed in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
- VII. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what happens will not agree with us. This is feedback, and how we respond to this feedback is key.

VIII. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?

- I have to do the reading.
- I have to do Thinking and mental model.
- I have to talk to competent people and understand their arguments.
- I have to think about the key variables and how they interact over time.
- I have to listen and chase down arguments that run counter to your views.
- I have to think about how you might be fooling yourself.
- I have to see the issue from multiple perspectives.
- I have to think.
- I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.

IX. If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."

X. We all are learning, modifying, or destroying ideas all the time. Rapid destruction of your ideas when the time is right is one of the most valuable qualities you can acquire. You must force yourself to consider arguments on the other side. As Rabbi Moses ben Maimon (1135–1204), commonly known as Maimonides, said: "Teach thy tongue to say I do not know, and thou shalt progress."

XI. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.

XII. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts that ran contrary to his ideas, he endeavored not only to listen but also not to rest until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

XIII. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

- Circle of Competence:

- **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve —after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time,

work to expand that circle but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

- The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.
 - The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
 - The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
 - How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge. Often they are veteran reporters who have specialized for years in a clearly defined area. They make a serious effort to understand the

complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

- Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful. Mimic and the Real Thing:
 - “There’s two kinds of snakes you come across. There’s the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it’s venomous, it can kill you in a minute. The Mexican Milk Snake can’t do anything to you; it’s an impostor.”How is it that these two look alike? It’s due to a phenomenon called Batesian Mimicry.
 - In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the “models”) were able to operate freely and relatively unmolested, there had also developed a “mimic” population of butterflies which wasn’t toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the “model” was and the more frequently they appeared in the local population, the easier it was for its “mimics” to get by! Predators simply wouldn’t take the risk of mixing up the two. If there aren’t as many “models” around or they aren’t that dangerous, the mimics have a harder time.
 - This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or “pretenders to the throne” are often very effective, very convincing “mimics” of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the “model,” the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many “future” Warren Buffett’s. For every Steve Jobs, there have been many “next” Steve Jobs’. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

XIV. The ability to destroy your ideas rapidly instead of slowly when the occasion is right is one of the most valuable things. You have to work hard on it. Ask yourself what are the arguments on the other side. It's bad to have an opinion you're proud of if you can't state the arguments for the other side better than your opponents. This is a great mental discipline.

XV. Doing the work means you can't make up your mind with a high degree of confidence right away. Doing the work forces you to challenge your beliefs because you have to argue from both sides. You become the somewhat impartial judge. What's on trial is your opinion. If you want to work with the world rather than against it, one of the major leverage points you can put effort into is how to distinguish between the people who've done the work and those who haven't. The ones who have will pass the Batesian Mimicry Test.

XVI. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.

XVII. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.

XVIII. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

XIX. We read a lot. I don't know anyone who's wise who doesn't read a lot. But that's not enough: You have to have a temperament to grab ideas and do sensible things. Most people don't grab the right ideas or don't know what to do with them.

XX. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. "Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day."

3. Step 3- Slow Down

I. Do Not Rush Thinking Process, and Do it Very Slow.

II. Do Not Rush Any Task I will do At Any Time.

III. Listen and Apply Book “The Slow Fix Solve Problems, Work Smarter, and Live Better in a World Addicted to Speed”

IV. Listen and Apply Book *In Praise Of Slowness Challenging the Cult of Speed BY Carl Honore.

- We live in a world scarce of understanding and abundant with information. We complain that we never have any free time yet we seek distraction. If work can't distract us, we distract ourselves. We crave perpetual stimulation and motion. We're so busy that our free time comes in 20 second bursts, just long enough for us to read the gist and assume we understand. If we are to synthesize learning and understanding we need time to think.
- The modern storm of bits and stimulation, relents only when we sleep. (And then only if we remember to turn off the phone.) Lost in all of this is the art of stillness. We live in a world with more information than ever and yet we understand less. We have come into the belief that the simple act of reading confers understanding. Worse, most of our reading is elementary reading, or skimming — a far cry from syntopical reading, which seems more fertile for the mind willing to do the work.
- But that's just it. We don't want, or can't find the time, to do the work that's required to hold an opinion. It's much easier to simply read the opinions of another and let them think for us.
- Understanding comes from focusing, chewing, and relentlessly ragging on a problem. It comes with false starts, dead ends, and frustration. Thinking requires time and space. It's slow. It means saying I don't know. In short, thinking is everything the modern workplace is designed to eradicate.
- We're expected to have an opinion about everything and yet our time to think is near zero. We hold more opinions than ever but have less understanding. We don't even understand ourselves. How could it be otherwise?
- As Milan Kundera wrote in his 1996 novella Slowness, “When things happen too fast, nobody can be certain about anything, about anything at all, not even about himself. “In our fast-moving modern world, it always

seems that the time-train is pulling out of the station just as we reach the platform. No matter how fast we go, no matter how cleverly we schedule, there are never enough hours in the day.”

- Carl Honore, wrote a book, In Praise of Slowness: Challenging the Cult of Speed, to explore why we’re always in such a rush, what if anything is the cure for time-sickness, and whether it’s desirable to slow down. The book is not an all-out declaration of war against speed. Speed has helped to remake our world in ways that are wonderful and liberating. Who wants to live without the Internet or jet travel? The problem is that our love of speed, our obsession with doing more and more in less and less time, has gone too far; it has turned into an addiction, a kind of idolatry. Even when speed starts to backfire, we invoke the go-faster gospel.
- When we rush, we skim the surface, and fail to make real connections with the world or other people.” Moreover we don’t make connections with ideas. We don’t synthesize. We don’t test theories over time. We don’t play with ideas.
- The implications on thinking are fascinating. We are all fast-thinkers now. We have forgotten how to look forward to things, and how to enjoy the moment when they arrive. Restaurants report that hurried diners increasingly pay the bill and order a taxi while eating dessert. Many fans leave sporting events early, no matter how close the score is, simply to steal a march on the traffic. Then there is the curse of multi-tasking. Doing two things at once seems so clever, so efficient, so modern. And yet what it often means is doing two things not very well. Like many people, I read the paper while watching TV— and find that I get less out of both. In this media-drenched, data-rich, channel-surfing, computer-gaming age, we have lost the art of doing nothing, of shutting out the background noise and distractions, of slowing down and simply being alone with our thoughts. Boredom— the word itself hardly existed 150 years ago— is a modern invention. Remove all stimulation, and we fidget, panic and look for something, anything, to do to make use of the time. When did you last see someone just gazing out the window on a train? Everyone is too busy reading the paper, playing video games, listening to iPods, working on the laptop, yammering into mobile phones. Instead of thinking deeply, or letting an idea simmer in the back of the mind, our instinct now is to reach for the

nearest sound bite. In modern warfare, correspondents in the field and pundits in the studio spew out instant analyses of events as they occur. Often their insights turn out to be wrong. But that hardly matters nowadays: in the land of speed, the man with the instant response is king. With satellite feeds and twenty-four-hour news channels, the electronic media is dominated by what one French sociologist dubbed “le fast thinker”— a person who can, without skipping a beat, summon up a glib answer to any question.

- Fast eats time. One consequence of fast is that we make poor decision after poor decision. Those decisions don’t go away never to be seen again. It’s not like we make a bad decision and we’re done with it. No, the consequences are much worse. Poor decisions eat time. They come back to haunt you. They create issue after issue. They feed into the perpetual motion machine of busyness. And in a culture where people wear busyness as a badge of honor bad decisions actually lead us to think that we’re doing more.

V. Do The Tasks Slowly, and Step By Step.

VI. The Art of Slowing down and Do Not Rush Anything.

- The Art of Stillness is a persuasively argued case for the pleasures of slowing down and being in one place. Today we’re going faster and faster in search of contentment and meaning. This is largely a recipe for ensuring we will never be happy. We have the sense, too often, of running at top speed and never being able to catch up.
- Too many of us see going nowhere as turning away from something rather than turning towards something.
- Going nowhere isn’t about turning your back on the world; it’s about stepping away now and then so that you can see the world more clearly and love it more deeply. “There is nothing either good or bad, but thinking makes it so.”
- The idea behind choosing to sit still long enough to learn about yourself is simple and has been around for ages. Marcus Aurelius and Epictetus reminded us many millennia ago that it’s how we respond to our experiences, not the experiences themselves, which shape us.

- The greatest weapon against stress is our ability to choose one thought over another. Part of making better decisions is making time to think. Something that few of us are able to do.
- “Our creations come not when we’re out in the world, gathering impressions, but when we’re sitting still, turning those impressions into sentences.

4. Step 4- Do not Multitask.

- I. Of course you can do more than one thing at once. The catch is you can’t do more more than one thing at once that requires concentration. You can walk and chew gum, but you can’t write an email and a report at the same time. When you’re doing two things at once that are cognitively demanding, what you’re really doing is switching back and forth very quickly from one task to another.
- II. There is a mental cost—called a switching cost—to all of this multitasking. But that’s not all it makes deep thinking impossible.
- III. I think people that multitask pay a huge price. They think they’re being extra productive, and I think they’re (out of their mind). I use the metaphor of the one-legged man in the ass-kicking contest. I think when you multi-task so much, you don’t have time to think about anything deeply. You’re giving the world an advantage you shouldn’t do. Practically everybody is drifting into that mistake. Concentrating hard on something that is important is. I can’t succeed at all without doing it. I did not succeed in life by intelligence. I succeeded because I have a long attention span.
- IV. It sounds counter-intuitive but if you want to increase discretionary time and reduce stress you need to schedule time to think. The tiny fragments of time many of us find ourselves with have a negative effect on our ability to think deeply about a problem. Furthermore they impede our ability to learn — we stay at a surface level and never move into a deep understanding. Deresiewicz warns: “You simply cannot (think) in bursts of 20 seconds at a time, constantly interrupted by Facebook messages or Twitter tweets, or fiddling with your iPod, or watching something on YouTube.”
- V. The opposite approach is to focus on a problem or subject and try to achieve a deep fluency. How many of us, however, have time? We don’t do the work required to have an opinion. Instead we operate with surface knowledge. We tackle problems with the first thought that comes to mind. Because we make a

poor initial decision, we spend countless hours attempting to correct it. No wonder we have no time to think. We're not heeding the advice of Joseph Tussman and letting the world do the work for us.

VI. Listen and Apply The Following Books:

- **The Multitasking Mind By Dario Saliveci**

5. Step 5-What is Thinking/

I. Thinking Rate

- You can't force yourself to think faster. If you try, you're likely to end up making much worse decisions. Here's how to improve the actual quality of your decisions instead of chasing hacks to speed them up.
- When the product of your job is your decisions, you might find yourself wanting to be able to make more decisions more quickly so you can be more productive overall.
- Chasing speed is a flawed approach. Because decisions—at least good ones—don't come out of thin air. They're supported by a lot of thinking.

II. Beyond The Hurry Culture

- Everyone is trying to work faster at all times, and they pressure everyone around them to work faster, too.
- All of these things increase pressure in the work environment and repeatedly reinforce the "hurry up!" message. They make managers feel like they're moving things along faster. That way if work isn't getting done, it's not their fault. But, DeMarco writes, they don't lead to meaningful changes in behavior that make the whole organization more productive. Speeding up often results in poor decisions that create future problems.
- The reason more pressure doesn't mean better productivity is that the rate at which we think is fixed. We can't force ourselves to start making faster decisions right now just because we're faced with an unrealistic deadline. DeMarco writes, *"Think rate is fixed. No matter what you do, no matter how hard you try, you can't pick up the pace of thinking."*

III. Elements of Effective Thinking

- **Understand Deeply.** Don't face complex issues head-on; first understand simple ideas deeply. Clear the clutter and expose what is really important. Be brutally honest about what you know and don't know. Then see what's missing, identify the gaps, and fill them in. Let go of bias, prejudice, and preconceived notions. There are degrees to understanding (it's not just a yes-or-no proposition) and you can always heighten yours. Rock-solid understanding is the foundation for success.
- **Make Mistakes.** Fail to succeed. Intentionally get it wrong to inevitably get it even more right. Mistakes are great teachers — they highlight unforeseen opportunities and holes in your understanding. They also show you which way to turn next, and they ignite your imagination.
- **Raise Questions.** Constantly create questions to clarify and extend your understanding. What's the real question? Working on the wrong questions can waste a lifetime. Ideas are in the air — the right questions will bring them out and help you see connections that otherwise would have been invisible.
- **Follow the Flow of Ideas.** Look back to see where ideas came from and then look ahead to discover where those ideas may lead. A new idea is a beginning, not an end. Ideas are rare— milk them. Following the consequences of small ideas can result in big payoffs. These are the four basic building blocks for effective thinking. The fifth is Change.
- **Change.** The unchanging element is change— by mastering the first four elements, you can change the way you think and learn. You can always improve, grow, and extract more out of your education, yourself, and the way you live your life. Change is the universal constant that allows you to get the most out of living and learning.

6. Step 6-Collect As Many mental models as Possible from diverse domains and academic disciplines That I think is suitable for my situation or Information provided by the Text, Book, Speech etc. Research a broad range of industries to identify mental models that can be integrated and Most Suitable into area of work or focus. In identifying the Great Mental Models we have to look for elementary principles, the ideas from multiple disciplines that form a time tested foundation, these mental models would be from Elementary Mental Models to most Advanced Mental Models. It may seem counterintuitive, to work on developing knowledge that is available to everyone, but the universe works in the same way no matter where you are in it or how you think the universe should be working. What you need is to understand the principles, so that when the details change you are still able to identify what is really going on. Listen and Follow Every Book on Each Mental models.

A. General Mental Models For Thinking.

I. The Great Mental Models Volume 1 By Fs Blog.

- The Map is Not The Territory.
- Circle of Competence.
- The first Principles Thinking.
- Though Experiment.
- Second Order Thinking.
- Probabilistic Thinking.
- Inversion.

- 7. Step 7-Getting familiar:** At this starting point, users decide if they can use an existing mental model (maybe one used for another similar product) or if they need to start from scratch. The existing mental model may be void of useful knowledge or worse, contain the wrong knowledge. The core components missing at this stage include an understanding of the language the product uses and the actionable steps needed to complete core tasks.
- 8. Step 8-Apply simple criteria to which mental models you use.** When selecting mental models to include into your own latticework, consider whether they support you to better understand yourself and/or the world around you, so you might better effective and impactful action. Also Mental models do two things: they help you assess how things work and they help you make better decisions. Ask some Questions:
 - I. How long has this model been around?** As a general rule, mental models which have been around for a long time (such as Occam's razor) will have been subjected to a great deal of scrutiny. Time is an excellent curator, trimming away inefficient ideas. A mental model which is new may not be particularly refined or versatile. Many of our mental models originate from Ancient Greece and Rome, meaning they have to be functional to have survived this long.
 - II. Is it a representation of reality?** In other words, does it reflect the real world? Or is it based on abstractions?
 - III. Does this model apply to multiple areas?** The more elastic a model is, the more valuable it is to learn about. (Of course, be careful not to apply the model where it doesn't belong. Mind Feynman: "You must not fool yourself, and you're the easiest person to fool.")
 - IV. How did this model originate?** Many mental models arise from scientific or mathematical concepts. The more fundamental the domain, the more likely the model is to be true and lasting.
 - V. Is it based on first principles?** A first principle is a foundational concept which cannot be deduced from any other concept and must be known.
 - VI. Does it require infinite regress?** Infinite regress refers to something which is justified by principles, which themselves require justification by other principles. A model based on infinite regress is likely to

required extensive knowledge of a particular topic, and have minimal real-world application.

9. **Step 9- *Becoming proficient*:** Users begin to understand the language of the situation or text, especially if this language uses technical or unfamiliar vernacular. Understanding terminology and use of product language is one of the first building blocks that form the foundation of the model. This is also when users start to understand the step-by-step procedures required to perform basic operations to get some desired outcome. Here, they are usually learning the bread-and-butter operations of the product so they can receive enough value to motivate them to keep using it. Later, they will be able to build on this knowledge.
10. **Step 10- Make connections between mental models.** We need to know full context and not isolated facts. Rather than holding siloed mental models in your mind, consider how they interact, connect and complement one another.
11. **Step 11-Think, what light the mental model can bring on the situation, idea, text , speech etc.** Do I see the situation, idea, text, speech etc, in the new way? What new way can I see the situation? Does This Makes easier to make a decision in my life?
12. **Step 12- Think very carefully, if each chosen Mental model applicable to situation, idea, text, speech etc.**
13. **Step 13-Use the Chosen Mental Models tool.** The canvas, below, will help you to identify high-value areas where new mental models can make the biggest impact on your work and life. It also provides a simple framework to begin to embed using your chosen models.
14. **Step 14-*Mastering*:** Users build on the core step-by-step tasks they already know, expanding their knowledge to more complex or niche capabilities. If they make it this far they most likely have an accurate understanding of most or all of the language the product uses.
15. **Step 15-Regularly reassess their priorities without fear of changing them.** They don't fall prey to inertia.
16. **Step 16-Be biased toward taking action—not lazily deferring.** If they encounter a mental model they value, they make sure they use it.
17. **Step 17-Be always looking to prove yourselves wrong.** Ego should not get in the way of mental models.

18. Step 18-Accepting that all models are wrong in certain instances is not a license to ignore the facts. As a society, we should search for better answers, look for evidence, and strive to increase the accuracy of our knowledge.

- I. That's not to say all lenses (or models) apply to all problems. They don't. And it's not to say that having more lenses (or models) will be a advantage in all problems. It won't. This is why learning and applying the Great Mental Models is a process that takes some work. But the truth is, most problems are multidimensional, and thus having more lenses often offers significant help with the problems we are facing.**
- II. The more you use them, the more you will be able to build the knowledge of indicators that can trigger the use of the most appropriate model. Using and failing, as long as you acknowledge, reflect, and learn from it, is also how you build your repertoire. You need to be deliberate about choosing the models you will use in a situation. As you use them, a great practice is to record and reflect. That way you can get better at both choosing models and applying them. Take the time to notice how you applied them, what the process was like, and what the results were. Over time you will develop your knowledge of which situations are best tackled through which models. Don't give up on a model if it doesn't help you right away. Learn more about it, and try to figure out exactly why it didn't work. It may be that you have to improve your understanding. Or there were aspects of the situation that you did not consider. Or that your focus was on the wrong variable.**

- 19. Step 19-After all Analysis, decide what models are the most suitable after all to apply.**
- 20. Step 20-Apply The Mental Model in Real Life or Reality, and let the world do the work for You.**

Step 65-Transdisciplinary Thinking

1. **Step 1 Define Transdisciplinary Thinking.** Transdisciplinary For one of the first times was stated in a 1973 OECD report on environmental education. Transdisciplinarity describes a study that focuses on issues that cross the borders of two or even more disciplines “when a common set of axioms prevail, related to but lying beyond and complementing traditional disciplines. With the other word, principles or techniques originally developed by one discipline but now commonly used by others. Transdisciplinarity is probably the most desirable and yet difficult to obtain form of integrated research. Some researchers are, in fact, skeptical about whether it can be achieved at all. For example, Pohl observes that the extent of the requirements for transdisciplinary research suggest that it is to some extent “a ‘megalomaniac’ endeavour.” In addition, Tress *et al.* note that, despite the best intentions, “Transdisciplinary landscape research is an exception, even interdisciplinarity is seldom reached.” Such studies seek a transcendence of disciplinary perspectives (in some cases “redrawing the disciplinary map” into a broader framework in “true systemic fashion” that involves practical engagement with “local and regional issues of concern”. In this sense transdisciplinarity is the highest form of integrated project, involving not only multiple disciplines, but also multiple *non-academic participants* (e.g., land managers, user groups, the general public) in a manner that combines interdisciplinarity with participatory approaches. Walter *et al.* suggest that transdisciplinary research is characterised by “a process of collaboration between scientists and non-scientists on a specific real world problem” and combines scientific research with the generation of decision-making capacity for the involved stakeholders or as Schmidt describes it a “problem with the problems”. While Mobjörk *et al.* suggest that transdisciplinarity can be divided into “consulting” (stakeholders are consulted but not incorporated in the research process) and “participatory” (stakeholders are incorporated and considered equally valuable) forms, we argue that non-participatory forms of transdisciplinarity are, in fact, interdisciplinarity as transdisciplinary approaches are widely defined by their engagement of non-scientists in the research process. The variety included in many transdisciplinary frameworks is largely the result of the strong problem solving

objectives of the research and the need for flexible methodologies in transdisciplinary research is driven by this problem solving approach as “methodologies employed in transdisciplinary research needs to correspond to and reflect the problem and context under investigation”. To ensure that all relevant disciplines are represented within transdisciplinary projects, a pluralistic (rather than unitary) approach to methodology is standard. This focus on the problem, rather than the disciplines excludes the possibility of unidirectional research. As Hadorn *et al.* observe, within a transdisciplinary environment, no single discipline has intellectual precedence. In fact, some researchers go so far as to equate transdisciplinarity with holism, arguing that “It solves disagreements and differences in knowledge and scientific approaches through dialectic thinking, not majority rule, tradition or compromise” [5] or that it is “a different manner of seeing the world, more systematic and more holistic”. As such, Rapport suggests that “the essential element of transdisciplinarity is ‘transcendence’—a creative process whereby a framework for characterizing larger level processes transcends frameworks used to characterize the parts”. (For more on creativity and serendipity involved in research that reaches beyond a single discipline.) Political ecology is an example of a transdisciplinary sub-discipline that has emerged from the transcendence of a number of disciplines—and has existed under the umbrella of a larger disciplinary body (Geography) since the 1970s though others associate with interdisciplinary work . In promoting a holistic perspective, transdisciplinarity requires considerable effort on the part of engaged researchers to open up their research to alternative ways of thinking, or, as Giri suggests to “overcome one’s disciplinary chauvinism” and develop “an openness to perspectives of other disciplines”. The adoption of a holistic perspective leads to another key feature of transdisciplinarity—that it has high aims of reconstituting and rearranging the nature of disciplinary knowledge thus creating, through fusion across arbitrary intellectual boundaries, new synthesized disciplines with which to address the real-world problems at hand explicitly through collaboration. The demands placed on researchers to collaborate and ‘overcome chauvinism’ means that transdisciplinarity, of all the integrated research forms, has a strong focus on the building of personal relationships and joint understandings. Establishing trust and understanding between researchers within the projects is thus a key objective of building

transdisciplinary capacity. Transdisciplinary working produces a new, novel form or way of working beyond the original disciplinary boundaries. It's like a cake: you can no longer see the form of the ingredients as they have taken on a different shape and flavour. Let's review the process that Pinker has laid out, one that we might think about emulating as we examine the causes of complex phenomena in human systems:

- III. We observe an interesting phenomenon in need of explanation, one we feel capable of exploring.
- IV. We propose and examine competing hypotheses that would explain the phenomena (set up in a falsifiable way, in harmony with the divide between science and pseudoscience laid out for us by the great Karl Popper).
- V. We examine a cross-section of: Empirical data relating to the phenomena; sensible qualitative inference (from multiple fields/disciplines, the more fundamental the better), and finally; "Demonstrable" aspects of nature we are nearly certain about, arising from controlled experiment or other rigorous sources of knowledge ranging from engineering to biology to cognitive neuroscience.
- VI. Listen and Apply The Following Books:
 - **How we can Assess the Level of Interdisciplinarity and Transdisciplinarity of Academic Institutions? By Mahmood Ramezanzade**
 - **Detection of Distributed Denial of Service (DDoS) Attacks in IOT Based Monitoring System of Banking Sector Using Machine Learning Models By Muhsmmmsf Shafiq**

2. Step 2-Do Work Required to Have an Opinion on Any Topic and Anything.

- I. Most people go through life not really getting any smarter. Why? They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
- II. You can acquire knowledge if you want it. In fact, there is a simple formula, which if followed is almost certain to make you smarter over time. Simple but not easy. It involves a lot of hard work. "The best thing a human being can do is to help another human being know more."
- III. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
- IV. Knowledge accumulation as an acquired, rather than natural, genius. And he'd give all the credit to the studying;.
- V. The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage ... the list goes on.
- VI. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some op-ed in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
- VII. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what happens will not agree with us. This is feedback, and how we respond to this feedback is key.

VIII. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?

- I have to do the reading.
- I have to do Thinking and mental model.
- I have to talk to competent people and understand their arguments.
- I have to think about the key variables and how they interact over time.
- I have to listen and chase down arguments that run counter to your views.
- I have to think about how you might be fooling yourself.
- I have to see the issue from multiple perspectives.
- I have to think.
- I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.

IX. If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."

X. We all are learning, modifying, or destroying ideas all the time. Rapid destruction of your ideas when the time is right is one of the most valuable qualities you can acquire. You must force yourself to consider arguments on the other side. As Rabbi Moses ben Maimon (1135–1204), commonly known as Maimonides, said: "Teach thy tongue to say I do not know, and thou shalt progress."

XI. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.

XII. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts that ran contrary to his ideas, he endeavored not only to listen but also not to rest until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

XIII. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

- Circle of Competence:

- **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve —after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time,

work to expand that circle but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

- The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.
 - The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
 - The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
 - How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge. Often they are veteran reporters who have specialized for years in a clearly defined area. They make a serious effort to understand the

complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

- Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful. Mimic and the Real Thing:
 - “There’s two kinds of snakes you come across. There’s the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it’s venomous, it can kill you in a minute. The Mexican Milk Snake can’t do anything to you; it’s an impostor.”How is it that these two look alike? It’s due to a phenomenon called Batesian Mimicry.
 - In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the “models”) were able to operate freely and relatively unmolested, there had also developed a “mimic” population of butterflies which wasn’t toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the “model” was and the more frequently they appeared in the local population, the easier it was for its “mimics” to get by! Predators simply wouldn’t take the risk of mixing up the two. If there aren’t as many “models” around or they aren’t that dangerous, the mimics have a harder time.
 - This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or “pretenders to the throne” are often very effective, very convincing “mimics” of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the “model,” the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many “future” Warren Buffett’s. For every Steve Jobs, there have been many “next” Steve Jobs’. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

XIV. The ability to destroy your ideas rapidly instead of slowly when the occasion is right is one of the most valuable things. You have to work hard on it. Ask yourself what are the arguments on the other side. It's bad to have an opinion you're proud of if you can't state the arguments for the other side better than your opponents. This is a great mental discipline.

XV. Doing the work means you can't make up your mind with a high degree of confidence right away. Doing the work forces you to challenge your beliefs because you have to argue from both sides. You become the somewhat impartial judge. What's on trial is your opinion. If you want to work with the world rather than against it, one of the major leverage points you can put effort into is how to distinguish between the people who've done the work and those who haven't. The ones who have will pass the Batesian Mimicry Test.

XVI. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.

XVII. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.

XVIII. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

XIX. We read a lot. I don't know anyone who's wise who doesn't read a lot. But that's not enough: You have to have a temperament to grab ideas and do sensible things. Most people don't grab the right ideas or don't know what to do with them.

XX. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. "Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day."

3. Step 3- Slow Down

I. Do Not Rush Thinking Process, and Do it Very Slow.

II. Do Not Rush Any Task I will do At Any Time.

III. Listen and Apply Book “The Slow Fix Solve Problems, Work Smarter, and Live Better in a World Addicted to Speed”

IV. Listen and Apply Book *In Praise Of Slowness Challenging the Cult of Speed BY Carl Honore.

- We live in a world scarce of understanding and abundant with information. We complain that we never have any free time yet we seek distraction. If work can't distract us, we distract ourselves. We crave perpetual stimulation and motion. We're so busy that our free time comes in 20 second bursts, just long enough for us to read the gist and assume we understand. If we are to synthesize learning and understanding we need time to think.
- The modern storm of bits and stimulation, relents only when we sleep. (And then only if we remember to turn off the phone.) Lost in all of this is the art of stillness. We live in a world with more information than ever and yet we understand less. We have come into the belief that the simple act of reading confers understanding. Worse, most of our reading is elementary reading, or skimming — a far cry from syntopical reading, which seems more fertile for the mind willing to do the work.
- But that's just it. We don't want, or can't find the time, to do the work that's required to hold an opinion. It's much easier to simply read the opinions of another and let them think for us.
- Understanding comes from focusing, chewing, and relentlessly ragging on a problem. It comes with false starts, dead ends, and frustration. Thinking requires time and space. It's slow. It means saying I don't know. In short, thinking is everything the modern workplace is designed to eradicate.
- We're expected to have an opinion about everything and yet our time to think is near zero. We hold more opinions than ever but have less understanding. We don't even understand ourselves. How could it be otherwise?
- As Milan Kundera wrote in his 1996 novella Slowness, “When things happen too fast, nobody can be certain about anything, about anything at all, not even about himself. “In our fast-moving modern world, it always

seems that the time-train is pulling out of the station just as we reach the platform. No matter how fast we go, no matter how cleverly we schedule, there are never enough hours in the day.”

- Carl Honore, wrote a book, In Praise of Slowness: Challenging the Cult of Speed, to explore why we’re always in such a rush, what if anything is the cure for time-sickness, and whether it’s desirable to slow down. The book is not an all-out declaration of war against speed. Speed has helped to remake our world in ways that are wonderful and liberating. Who wants to live without the Internet or jet travel? The problem is that our love of speed, our obsession with doing more and more in less and less time, has gone too far; it has turned into an addiction, a kind of idolatry. Even when speed starts to backfire, we invoke the go-faster gospel.
- When we rush, we skim the surface, and fail to make real connections with the world or other people.” Moreover we don’t make connections with ideas. We don’t synthesize. We don’t test theories over time. We don’t play with ideas.
- The implications on thinking are fascinating. We are all fast-thinkers now. We have forgotten how to look forward to things, and how to enjoy the moment when they arrive. Restaurants report that hurried diners increasingly pay the bill and order a taxi while eating dessert. Many fans leave sporting events early, no matter how close the score is, simply to steal a march on the traffic. Then there is the curse of multi-tasking. Doing two things at once seems so clever, so efficient, so modern. And yet what it often means is doing two things not very well. Like many people, I read the paper while watching TV— and find that I get less out of both. In this media-drenched, data-rich, channel-surfing, computer-gaming age, we have lost the art of doing nothing, of shutting out the background noise and distractions, of slowing down and simply being alone with our thoughts. Boredom— the word itself hardly existed 150 years ago— is a modern invention. Remove all stimulation, and we fidget, panic and look for something, anything, to do to make use of the time. When did you last see someone just gazing out the window on a train? Everyone is too busy reading the paper, playing video games, listening to iPods, working on the laptop, yammering into mobile phones. Instead of thinking deeply, or letting an idea simmer in the back of the mind, our instinct now is to reach for the

nearest sound bite. In modern warfare, correspondents in the field and pundits in the studio spew out instant analyses of events as they occur. Often their insights turn out to be wrong. But that hardly matters nowadays: in the land of speed, the man with the instant response is king. With satellite feeds and twenty-four-hour news channels, the electronic media is dominated by what one French sociologist dubbed “le fast thinker”— a person who can, without skipping a beat, summon up a glib answer to any question.

- Fast eats time. One consequence of fast is that we make poor decision after poor decision. Those decisions don’t go away never to be seen again. It’s not like we make a bad decision and we’re done with it. No, the consequences are much worse. Poor decisions eat time. They come back to haunt you. They create issue after issue. They feed into the perpetual motion machine of busyness. And in a culture where people wear busyness as a badge of honor bad decisions actually lead us to think that we’re doing more.

V. Do The Tasks Slowly, and Step By Step.

VI. The Art of Slowing down and Do Not Rush Anything.

- The Art of Stillness is a persuasively argued case for the pleasures of slowing down and being in one place. Today we’re going faster and faster in search of contentment and meaning. This is largely a recipe for ensuring we will never be happy. We have the sense, too often, of running at top speed and never being able to catch up.
- Too many of us see going nowhere as turning away from something rather than turning towards something.
- Going nowhere isn’t about turning your back on the world; it’s about stepping away now and then so that you can see the world more clearly and love it more deeply. “There is nothing either good or bad, but thinking makes it so.”
- The idea behind choosing to sit still long enough to learn about yourself is simple and has been around for ages. Marcus Aurelius and Epictetus reminded us many millennia ago that it’s how we respond to our experiences, not the experiences themselves, which shape us.

- The greatest weapon against stress is our ability to choose one thought over another. Part of making better decisions is making time to think. Something that few of us are able to do.
- “Our creations come not when we’re out in the world, gathering impressions, but when we’re sitting still, turning those impressions into sentences.

4. Step 4- Do not Multitask.

- I. Of course you can do more than one thing at once. The catch is you can’t do more more than one thing at once that requires concentration. You can walk and chew gum, but you can’t write an email and a report at the same time. When you’re doing two things at once that are cognitively demanding, what you’re really doing is switching back and forth very quickly from one task to another.
- II. There is a mental cost—called a switching cost—to all of this multitasking. But that’s not all it makes deep thinking impossible.
- III. I think people that multitask pay a huge price. They think they’re being extra productive, and I think they’re (out of their mind). I use the metaphor of the one-legged man in the ass-kicking contest. I think when you multi-task so much, you don’t have time to think about anything deeply. You’re giving the world an advantage you shouldn’t do. Practically everybody is drifting into that mistake. Concentrating hard on something that is important is. I can’t succeed at all without doing it. I did not succeed in life by intelligence. I succeeded because I have a long attention span.
- IV. It sounds counter-intuitive but if you want to increase discretionary time and reduce stress you need to schedule time to think. The tiny fragments of time many of us find ourselves with have a negative effect on our ability to think deeply about a problem. Furthermore they impede our ability to learn — we stay at a surface level and never move into a deep understanding. Deresiewicz warns: “You simply cannot (think) in bursts of 20 seconds at a time, constantly interrupted by Facebook messages or Twitter tweets, or fiddling with your iPod, or watching something on YouTube.”
- V. The opposite approach is to focus on a problem or subject and try to achieve a deep fluency. How many of us, however, have time? We don’t do the work required to have an opinion. Instead we operate with surface knowledge. We tackle problems with the first thought that comes to mind. Because we make a

poor initial decision, we spend countless hours attempting to correct it. No wonder we have no time to think. We're not heeding the advice of Joseph Tussman and letting the world do the work for us.

VI. Listen and Apply The Following Books:

- **The Multitasking Mind By Dario Saliveci**

5. Step 5-What is Thinking?

I. Thinking Rate

- You can't force yourself to think faster. If you try, you're likely to end up making much worse decisions. Here's how to improve the actual quality of your decisions instead of chasing hacks to speed them up.
- When the product of your job is your decisions, you might find yourself wanting to be able to make more decisions more quickly so you can be more productive overall.
- Chasing speed is a flawed approach. Because decisions—at least good ones—don't come out of thin air. They're supported by a lot of thinking.

II. Beyond The Hurry Culture

- Everyone is trying to work faster at all times, and they pressure everyone around them to work faster, too.
- All of these things increase pressure in the work environment and repeatedly reinforce the "hurry up!" message. They make managers feel like they're moving things along faster. That way if work isn't getting done, it's not their fault. But, DeMarco writes, they don't lead to meaningful changes in behavior that make the whole organization more productive. Speeding up often results in poor decisions that create future problems.
- The reason more pressure doesn't mean better productivity is that the rate at which we think is fixed. We can't force ourselves to start making faster decisions right now just because we're faced with an unrealistic deadline. DeMarco writes, *"Think rate is fixed. No matter what you do, no matter how hard you try, you can't pick up the pace of thinking."*

III. Elements of Effective Thinking

- **Understand Deeply.** Don't face complex issues head-on; first understand simple ideas deeply. Clear the clutter and expose what is really important. Be brutally honest about what you know and don't know. Then see what's missing, identify the gaps, and fill them in. Let go of bias, prejudice, and preconceived notions. There are degrees to understanding (it's not just a yes-or-no proposition) and you can always heighten yours. Rock-solid understanding is the foundation for success.
- **Make Mistakes.** Fail to succeed. Intentionally get it wrong to inevitably get it even more right. Mistakes are great teachers — they highlight unforeseen opportunities and holes in your understanding. They also show you which way to turn next, and they ignite your imagination.
- **Raise Questions.** Constantly create questions to clarify and extend your understanding. What's the real question? Working on the wrong questions can waste a lifetime. Ideas are in the air — the right questions will bring them out and help you see connections that otherwise would have been invisible.
- **Follow the Flow of Ideas.** Look back to see where ideas came from and then look ahead to discover where those ideas may lead. A new idea is a beginning, not an end. Ideas are rare— milk them. Following the consequences of small ideas can result in big payoffs. These are the four basic building blocks for effective thinking. The fifth is Change.
- **Change.** The unchanging element is change— by mastering the first four elements, you can change the way you think and learn. You can always improve, grow, and extract more out of your education, yourself, and the way you live your life. Change is the universal constant that allows you to get the most out of living and learning.

6. Step 6-Collect As Many mental models as Possible from diverse domains and academic disciplines That I think is suitable for my situation or Information provided by the Text, Book, Speech etc. Research a broad range of industries to identify mental models that can be integrated and Most Suitable into area of work or focus. In identifying the Great Mental Models we have to look for elementary principles, the ideas from multiple disciplines that form a time tested foundation, these mental models would be from Elementary Mental Models to most Advanced Mental Models. It may seem counterintuitive, to work on developing knowledge that is available to everyone, but the universe works in the same way no matter where you are in it or how you think the universe should be working. What you need is to understand the principles, so that when the details change you are still able to identify what is really going on. Listen and Follow Every Book on Each Mental models.

7. **Step 7-Getting familiar:** At this starting point, users decide if they can use an existing mental model (maybe one used for another similar product) or if they need to start from scratch. The existing mental model may be void of useful knowledge or worse, contain the wrong knowledge. The core components missing at this stage include an understanding of the language the product uses and the actionable steps needed to complete core tasks.
8. **Step 8-Apply simple criteria to which mental models you use.** When selecting mental models to include into your own latticework, consider whether they support you to better understand yourself and/or the world around you, so you might better effective and impactful action. Also Mental models do two things: they help you assess how things work and they help you make better decisions. Ask some Questions:
 - I. How long has this model been around? As a general rule, mental models which have been around for a long time (such as Occam's razor) will have been subjected to a great deal of scrutiny. Time is an excellent curator, trimming away inefficient ideas. A mental model which is new may not be particularly refined or versatile. Many of our mental models originate from Ancient Greece and Rome, meaning they have to be functional to have survived this long.
 - II. Is it a representation of reality? In other words, does it reflect the real world? Or is it based on abstractions?
 - III. Does this model apply to multiple areas? The more elastic a model is, the more valuable it is to learn about. (Of course, be careful not to apply the model where it doesn't belong. Mind Feynman: "You must not fool yourself, and you're the easiest person to fool.")
 - IV. How did this model originate? Many mental models arise from scientific or mathematical concepts. The more fundamental the domain, the more likely the model is to be true and lasting.
 - V. Is it based on first principles? A first principle is a foundational concept which cannot be deduced from any other concept and must be known.
 - VI. Does it require infinite regress? Infinite regress refers to something which is justified by principles, which themselves require justification by other principles. A model based on infinite regress is likely to

required extensive knowledge of a particular topic, and have minimal real-world application.

9. **Step 9- *Becoming proficient*:** Users begin to understand the language of the situation or text, especially if this language uses technical or unfamiliar vernacular. Understanding terminology and use of product language is one of the first building blocks that form the foundation of the model. This is also when users start to understand the step-by-step procedures required to perform basic operations to get some desired outcome. Here, they are usually learning the bread-and-butter operations of the product so they can receive enough value to motivate them to keep using it. Later, they will be able to build on this knowledge.
10. **Step 10- Make connections between mental models.** We need to know full context and not isolated facts. Rather than holding siloed mental models in your mind, consider how they interact, connect and complement one another.
11. **Step 11-Think, what light the mental model can bring on the situation, idea, text , speech etc.** Do I see the situation, idea, text, speech etc, in the new way? What new way can I see the situation? Does This Makes easier to make a decision in my life?
12. **Step 12- Think very carefully, if each chosen Mental model applicable to situation, idea, text, speech etc.**
13. **Step 13-Use the Chosen Mental Models tool.** The canvas, below, will help you to identify high-value areas where new mental models can make the biggest impact on your work and life. It also provides a simple framework to begin to embed using your chosen models.
14. **Step 14-*Mastering*:** Users build on the core step-by-step tasks they already know, expanding their knowledge to more complex or niche capabilities. If they make it this far they most likely have an accurate understanding of most or all of the language the product uses.
15. **Step 15-Regularly reassess their priorities without fear of changing them.** They don't fall prey to inertia.
16. **Step 16-Be biased toward taking action—not lazily deferring.** If they encounter a mental model they value, they make sure they use it.
17. **Step 17-Be always looking to prove yourselves wrong.** Ego should not get in the way of mental models.

18. Step 18-Accepting that all models are wrong in certain instances is not a license to ignore the facts. As a society, we should search for better answers, look for evidence, and strive to increase the accuracy of our knowledge.

- I. That's not to say all lenses (or models) apply to all problems. They don't. And it's not to say that having more lenses (or models) will be a advantage in all problems. It won't. This is why learning and applying the Great Mental Models is a process that takes some work. But the truth is, most problems are multidimensional, and thus having more lenses often offers significant help with the problems we are facing.**
- II. The more you use them, the more you will be able to build the knowledge of indicators that can trigger the use of the most appropriate model. Using and failing, as long as you acknowledge, reflect, and learn from it, is also how you build your repertoire. You need to be deliberate about choosing the models you will use in a situation. As you use them, a great practice is to record and reflect. That way you can get better at both choosing models and applying them. Take the time to notice how you applied them, what the process was like, and what the results were. Over time you will develop your knowledge of which situations are best tackled through which models. Don't give up on a model if it doesn't help you right away. Learn more about it, and try to figure out exactly why it didn't work. It may be that you have to improve your understanding. Or there were aspects of the situation that you did not consider. Or that your focus was on the wrong variable.**

- 19. Step 19-After all Analysis, decide what models are the most suitable after all to apply.**
- 20. Step 20-Apply The Mental Model in Real Life or Reality, and let the world do the work for You.**

Step 66-Journaling

1. **Step 1-So keep a journal. Write your experiences down. When you identify a model at work in the world, write that down too. Then you can explore the applications you've observed, and start being more in control of the models you use every day. For instance, instead of falling victim to confirmation bias, you will be able to step back and see it at work in yourself and others. Once you get practice, you will start to naturally apply models as you go through your life, from reading the news to contemplating a career move. As we have seen, we can run into problems when we apply models to situations in which they don't fit. If a model works, we must invest the time and energy into understanding why it worked so we know when to use**
2. **Visualization- Remember, visualization will never compensate for the work undone. You cannot visualize lies. All the strategies I employ to answer the simple questions and win the mind game are effective because I put in work. It's a lot more than mind over matter. It takes relentless self-discipline to schedule suffering into your day, every day, but if you do, you'll find that at the other end of that suffering is a whole other life just waiting for you.**
 - **First, he would learn everything he could about it and prepare physically as best as possible.**
 - **Once the physical prep was done, he'd take care of the mental prep with visualization.**
 - **Since he knew almost everything about his challenge, he visualized what awaited him. He would imagine himself struggling, suffering, and eventually succeeding.**
 - **Preparing himself this way helped him pace his future, and improve the odds of avoiding quitting.**
 - **Side note: visualization is great, but it's no substitute for preparation.**

Step 67-Letting The World Do The Work For You

1. Listen and Apply book

III. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works

2. **The world never tells you that you're wrong; it only gives you outcomes.**
3. **Don't force. Don't resist. Have a beginner's mind. Let the world teach you.**
4. **Reality will do a lot of the work for us if we simply align with it. Most of the time we're simply adding friction because we want the world to work in the way we think it should.**
5. **If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman**
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.
7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or

circumstances. If you want to align yourself with reality, you have to work at it and care about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.

- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.
- IV. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.
- V. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
- VI. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
- VII. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.
- VIII. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding

how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

- IX. 2nd Order Thinking. One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself "If I do X, what will happen *after* that?". I sum this up using the ecologist Garrett Hardin's simple question: "And then what?" A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it. We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves "And then what?" We don't ask what other solutions might be even *more* optimal. For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve. Optically, they "reorganize their incentive programs," but practically, they've simply expended energy to stay in place. Another, perhaps more complicated,

example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He's got all these beautiful charts on how much more competitive you'll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You're sold. Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitor's door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins. We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn't always a comfortable reality. Understanding how the world works isn't easy and it shouldn't be. It's hard work. If it were easy, everyone would do it. And it's not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it's extremely helpful to understand the forces at play outside of their narrow area of expertise. Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

- X. When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don't line up with reality as we think something that isn't true.
- XI. We must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we've got all the information, if we're on the ship, the fish in the ocean has more he can share. The second flaw is ego. Many of us tend to have too much invested in our opinions of ourselves to see the world's feedback—the feedback we need to update our beliefs about reality. This creates a profound ignorance that keeps us banging our head against the wall over and over again. Our inability to learn from the world because of our ego happens for many reasons, but two are worth mentioning here. First, we're so

afraid about what others will say about us that we fail to put our ideas out there and subject them to criticism. This way we can always be right. Second, if we do put our ideas out there and they are criticized, our ego steps in to protect us. We become invested in defending instead of upgrading our ideas. The third flaw is distance. The further we are from the results of our decisions, the easier it is to keep our current views rather than update them. When you put your hand on a hot stove, you quickly learn the natural consequence. You pay the price for your mistakes. Since you are a pain avoiding creature, you update your view. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding

Step 68-Journaling

1. **Step 1-So keep a journal. Write your experiences down. When you identify a model at work in the world, write that down too. Then you can explore the applications you've observed, and start being more in control of the models you use every day. For instance, instead of falling victim to confirmation bias, you will be able to step back and see it at work in yourself and others. Once you get practice, you will start to naturally apply models as you go through your life, from reading the news to contemplating a career move. As we have seen, we can run into problems when we apply models to situations in which they don't fit. If a model works, we must invest the time and energy into understanding why it worked so we know when to use**
2. **Visualization- Remember, visualization will never compensate for the work undone. You cannot visualize lies. All the strategies I employ to answer the simple questions and win the mind game are effective because I put in work. It's a lot more than mind over matter. It takes relentless self-discipline to schedule suffering into your day, every day, but if you do, you'll find that at the other end of that suffering is a whole other life just waiting for you.**
 - **First, he would learn everything he could about it and prepare physically as best as possible.**
 - **Once the physical prep was done, he'd take care of the mental prep with visualisation.**
 - **Since he knew almost everything about his challenge, he visualized what awaited him. He would imagine himself struggling, suffering, and eventually succeeding.**
 - **Preparing himself this way helped him pace his future, and improve the odds of avoiding quitting.**
 - **Side note: visualisation is great, but it's no substitute for preparation.**

Step 69-Letting The World Do The Work For You

1. Listen and Apply book

XII. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works

2. **The world never tells you that you're wrong; it only gives you outcomes.**
3. **Don't force. Don't resist. Have a beginner's mind. Let the world teach you.**
4. **Reality will do a lot of the work for us if we simply align with it. Most of the time we're simply adding friction because we want the world to work in the way we think it should.**
5. **If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman**
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.
7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or

circumstances. If you want to align yourself with reality, you have to work at it and care about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.

- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.
- IV. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.
- V. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
- VI. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
- VII. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding.

PART 8: Simplify Explanation and Creating Analogies

Step 70-Simplify your explanations and create analogies. Streamline your notes and explanation, further clarifying the topic until it seems obvious.

- I. **Simplify your explanations and create analogies. Streamline your notes and explanation, further clarifying the topic until it seems obvious. Additionally, think of analogies that feel intuitive.**
 - A. Every field of study has its own specialised terms. While it may be important to know them, it's also important to not confuse knowing jargon with knowing concepts. The Feynman Technique involves simplifying our initial explanations and refining our understanding through simple analogies..Why this step works:
 - B. Simplicity is a proxy for understanding. It's easy enough to commit terms to memory, and repeat them back when prompted. But memorisation is not understanding. When we can't rely on big words that make us sound smart, we have to distill what we truly know to the most basic form. This is where true understanding takes place.
 - C. Analogies are easier to recall and explain. When you understand a challenging concept, analogies allow you to create a short-hand for recalling it quickly and explaining it to others clearly. Learning material often provides ready-made analogies for us. For example, we all probably have "the mitochondria are the powerhouse of the cell" burned into our collective memories. However, pushing ourselves to create our own analogies is even more powerful than regurgitating a borrowed one that we may not actually understand.

PART 9: Reflect, Refine and Simplify

Step 71-Reflect, Refine, and Simplify.

I. Reflect, Refine, and Simplify.

- A. Only when you can explain the subject in simple terms do you understand it.**
- B. Simple is beautiful.**
- C. Review your notes to make sure you didn't mistakenly borrow any jargon or gloss over anything complicated.**
- D. Read it out loud as if to a child. If the explanation isn't simple enough or sounds confusing, that's a good indication that you need to reflect and refine.**
- E. Go back to the source material, reviewing the parts you don't quite understand yet.**
- F. Repeat until you have a simple explanation.**

PART 10: Organise And Review.

Step 72 - Organise And Review.

I. Organize and Review

- A. To test your understanding in the real world, run it by someone else. How effective was your explanation? What questions did they ask? What parts did they get confused about?
- B. When you're happy with your understanding, take the page you created with a simple explanation and put it into a binder. Following this technique for everything you learn gives you a binder full of learning that you can review a couple of times a year.

PART 11: Deep Work and Application

Step 73 - The Focus to Say No

1. The difference between average results and exceptional ones is what you avoid. Saying no to mediocre opportunities is easy. Saying no to good opportunities is hard.
2. We all have the same number of hours in a week. What separates people is how they use them. You can do anything, but you can't do everything.
3. The Hidden Cost of Yes
 - I. Saying yes creates an obligation. Saying yes commits you to something. The things we say yes to have a habit of growing.
 - II. Saying yes should make the future easier, not harder.
 - III. Saying yes to a request feels good in the moment. So we say yes to things we know won't move us forward. We say yes because we don't want to hurt someone's feelings. We say yes to be polite. We say yes out of obligation. We say yes because we 'should.'
4. When dealing with anyone other than friends or family, saying yes should ultimately lead to results.
5. Saying yes carries a cost that is often paid in the days, weeks, or even years ahead. What starts as a single meeting becomes a weekly one. A small project becomes a large one. A one-time event with colleagues turns into a weekly session.
6. Be quick to say no and slow to say yes. Saying yes consumes time, saying no creates time. Never say yes on the spot. Always give yourself some space. Make it a rule. Tell people. That's what Daniel Kahneman does. When he's on the phone he says 'my rule is I never say yes on the phone. I'll email you later after I think about it more.' And when I asked him how often he later says yes, he responded 'rarely.'

Step 74-Half Life. The Decay of Knowledge and What to Do About It.

1. The Decay of Knowledge and What to Do About It.

- I. **The Basics-**A half-life is the time taken for something to halve its quantity. The term is most often used in the context of radioactive decay, which occurs when unstable atomic particles lose energy. Twenty-nine elements are known to be capable of undergoing this process. Information also has a half-life, as do drugs, marketing campaigns, and all sorts of other things. We see the concept in any area where the quantity or strength of something decreases over time. Radioactive decay is random, and measured half-lives are based on the most probable rate. We know that a nucleus will decay at some point; we just cannot predict when. It could be anywhere between instantaneous and the total age of the universe. Although scientists have defined half-lives for different elements, the exact rate is completely random. Half-lives of elements vary tremendously. For example, carbon takes millions of years to decay; that's why it is stable enough to be a component of the bodies of living organisms. Different isotopes of the same element can also have different half-lives. Three main types of nuclear decay have been identified: alpha, beta, and gamma. Alpha decay occurs when a nucleus splits into two parts: a helium nucleus and the remainder of the original nucleus. Beta decay occurs when a neutron in the nucleus of an element changes into a proton. The result is that it turns into a different element, such as when potassium decays into calcium. Beta decay also releases a neutrino — a particle with virtually no mass. If a nucleus emits radiation without experiencing a change in its composition, it is subject to gamma decay. Gamma radiation contains an enormous amount of energy.
- II. **The Discovery of Half-Lives.** The discovery of half-lives (and alpha and beta radiation) is credited to Ernest Rutherford, one of the most influential physicists of his time. Rutherford was at the forefront of this major

discovery when he worked with physicist Joseph John Thompson on complementary experiments leading to the discovery of electrons. Rutherford recognized the potential of what he was observing and began researching radioactivity. Two years later, he identified the distinction between alpha and beta rays. This led to his discovery of half-lives, when he noticed that samples of radioactive materials took the same amount of time to decay by half. By 1902, Rutherford and his collaborators had a coherent theory of radioactive decay (which they called “atomic disintegration”). They demonstrated that radioactive decay enabled one element to turn into another — research which would earn Rutherford a Nobel Prize. A year later, he spotted the missing piece in the work of the chemist Paul Villard and named the third type of radiation gamma. Half-lives are based on probabilistic thinking. If the half-life of an element is seven days, it is most probable that half of the atoms will have decayed in that time. For a large number of atoms, we can expect half-lives to be fairly consistent. It’s important to note that radioactive decay is based on the element itself, not the quantity of it. By contrast, in other situations, the half-life may vary depending on the amount of material. For example, the half-life of a chemical someone ingests might depend on the quantity. In biology, a half-life is the time taken for a substance to lose half its effects. The most obvious instance is drugs; the half-life is the time it takes for their effect to halve, or for half of the substance to leave the body. The half-life of caffeine is around 6 hours, but (as with most biological half-lives) numerous factors can alter that number. People with compromised liver function or certain genes will take longer to metabolize caffeine. Consumption of grapefruit juice has been shown in some studies to slow caffeine metabolism. It takes around 24 hours for a dose of caffeine to fully leave the body. The half-lives of drugs vary from a few seconds to several weeks. To complicate matters, biological half-lives vary for different parts of the body. Lead has a half-life of around a month in the blood, but a decade in bone. Plutonium in bone has a half-life of a century — more than double the time for the liver. Marketers refer to the half-life of a campaign — the time taken to receive half the total responses. Unsurprisingly, this time varies among media. A paper catalog may have a half-life of about three weeks, whereas a tweet might have a half-life of a few minutes. Calculating

this time is important for establishing how frequently a message should be sent.

III. The Half-Life of Facts-In *The Half-Life of Facts: Why Everything We Know Has an Expiration Date*, Samuel Arbesman (see our [Knowledge Project interview](#)) posits that facts decay over time until they are no longer facts or perhaps no longer complete. According to Arbesman, information has a predictable half-life: the time taken for half of it to be replaced or disproved. Over time, one group of facts replaces another. As our tools and knowledge become more advanced, we can discover more — sometimes new things that contradict what we thought we knew, sometimes nuances about old things. Sometimes we discover a whole area that we didn't know about. The rate of these discoveries varies. Our body of engineering knowledge changes more slowly, for example, than does our body of psychological knowledge. Arbesman studied the nature of facts. The field was born in 1947, when mathematician Derek J. de Solla Price was arranging a set of philosophical books on his shelf. Price noted something surprising: the sizes of the books fit an exponential curve. His curiosity piqued, he began to see whether the same curve applied to science as a whole. Price established that the quantity of scientific data available was doubling every 15 years. This meant that some of the information had to be rendered obsolete with time. Scientometrics shows us that facts are always changing, and much of what we know is (or soon will be) incorrect. Indeed, much of the available published research, however often it is cited, has never been reproduced and cannot be considered true. In a controversial paper entitled "[Why Most Published Research Findings Are False](#)," John Ioannides covers the rampant nature of poor science. Many researchers are incentivized to find results that will please those giving them funding. Intense competition makes it essential to find new information, even if it is found in a dubious manner. Yet we all have a tendency to turn a blind eye when beliefs we hold dear are disproved and to pay attention only to information confirming our existing opinions. As an example, Arbesman points to the number of chromosomes in a human cell. Up until 1965, 48 was the accepted number that medical students were taught. (In 1953, it had been declared an established fact by a leading cytologist). Yet in 1956,

two researchers, Joe Hin Tjio and Albert Levan, made a bold assertion. They declared the true number to be 46. During their research, Tjio and Levan could never find the number of chromosomes they expected. Discussing the problem with their peers, they discovered they were not alone. Plenty of other researchers found themselves two chromosomes short of the expected 48. Many researchers even abandoned their work because of this perceived error. But Tjio and Levan were right (for now, anyway). Although an extra two chromosomes seems like a minor mistake, we don't know the opportunity costs of the time researchers invested in faulty hypotheses or the value of the work that was abandoned. It was an emperor's-new-clothes situation, and anyone counting 46 chromosomes assumed they were the ones making the error. As Arbesman puts it, facts change incessantly. Many of us have seen the ironic (in hindsight) doctor-endorsed cigarette ads from the past. A glance at a newspaper will doubtless reveal that meat or butter or sugar has gone from deadly to saintly, or vice versa. We forget that laughable, erroneous beliefs people once held are not necessarily any different from those we now hold. The people who believed that the earth was the center of the universe, or that some animals appeared out of nowhere or that the earth was flat, were not stupid. They just believed facts that have since decayed. Arbesman gives the example of a dermatology test that had the same question two years running, with a different answer each time. This is unsurprising considering the speed at which our world is changing. As Arbesman points out, in the last century the world's population has swelled from 2 billion to 7 billion, we have taken on space travel, and we have altered the very definition of science. The order Arbesman describes mimics the decay of radioactive elements. Whenever new information is discovered, we can be sure it will break down and be proved wrong at some point. As with a radioactive atom, we don't know precisely when that will happen, but we know it will occur at some point. If we zoom out and look at a particular body of knowledge, the random decay becomes orderly. Through probabilistic thinking, we can predict the half-life of a group of facts with the same certainty with which we can predict the half-life of a radioactive atom. The problem is that we rarely consider the half-life of information. Many people assume that whatever they learned in school remains true years or decades

later. Medical students who learned in university that cells have 48 chromosomes would not learn later in life that this is wrong unless they made an effort to do so. OK, so we know that our knowledge will decay. What do we do with this information? Arbesman says, Simply knowing that knowledge changes like this isn't enough. We would end up going a little crazy as we frantically tried to keep up with the ever changing facts around us, forever living on some sort of informational treadmill. But it doesn't have to be this way because there are patterns. Facts change in regular and mathematically understandable ways. And only by knowing the pattern of our knowledge evolution can we be better prepared for its change. Recent initiatives have sought to calculate the half-life of an academic paper. Ironically, academic journals have largely neglected research into how people use them and how best to fund the efforts of researchers. Research by Philip Davis shows the time taken for a paper to receive half of its total downloads. Davis's results are compelling. While most forms of media have a half-life measured in days or even hours, 97 percent of academic papers have a half-life longer than a year. Engineering papers have a slightly shorter half-life than other fields of research, with double the average (6 percent) having a half-life of under a year. This makes sense considering what we looked at earlier in this post. Health and medical publications have the shortest overall half-life: two to three years. Physics, mathematics, and humanities publications have the longest half-lives: two to four years.

- IV. The Half-Life of Secrets-According to Peter Swire, writing in "The Declining Half-Life of Secrets," the half-life of secrets (by which Swire generally means classified information) is shrinking. In the past, a government secret could be kept for over 25 years. Nowadays, hacks and leaks have shrunk that time considerably. Swire writes: Swire notes that there are three main causes: "the continuing effects of Moore's Law — or the idea that computing power doubles every two years, the sociology of information technologists, and the different source and methods for signals intelligence today compared with the Cold War." One factor is that spreading leaked information is easier than ever. In the past, it was often difficult to get information published. Newspapers feared legal repercussions if they shared classified information. Anyone can now release secret information,

often anonymously, as with WikiLeaks. Governments cannot as easily rely on media gatekeepers to cover up leaks. Rapid changes in technology or geopolitics often reduce the value of classified information, so the value of some, but not all, classified information also has a half-life. Sometimes it's days or weeks, and sometimes it's years. For some secrets, it's not worth investing the massive amount of computer time that would be needed to break them because by the time you crack the code, the information you wanted to know might have expired. (As an aside, if you were to invert the problem of all these credit card and SSN leaks, you might conclude that reducing the value of possessing this information would be more effective than spending money to secure it.)

- V. The Half-Lives of Careers and Business Models. The issue with information having a half-life should be obvious. Many fields depend on individuals with specialized knowledge, learned through study or experience or both. But what if those individuals are failing to keep up with changes and clinging to outdated facts? What if your doctor is offering advice that has been rendered obsolete since they finished medical school? What if your own degree or qualifications are actually useless? These are real problems, and knowing about half-lives will help you make yourself more adaptable. While figures for the half-lives of most knowledge-based careers are hard to find, we do know the half-life of an engineering career. A century ago, it would take 35 years for half of what an engineer learned when earning their degree to be disproved or replaced. By the 1960s, that time span shrank to a mere decade. Today that figure is probably even lower. In 1966 paper entitled "The Dollars and Sense of Continuing Education," Thomas Jones calculated the effort that would be required for an engineer to stay up to date, assuming a 10-year half-life. According to Jones, an engineer would need to devote at least five hours per week, 48 weeks a year, to stay up to date with new advancements. A typical degree requires about 4800 hours of work. Within 10 years, the information learned during 2400 of those hours would be obsolete. The five-hour figure does not include the time necessary to revise forgotten information that is still relevant. A 40-year career as an engineer would require 9600 hours of independent study. Keep in mind that Jones made his calculations in the 1960s. Modern estimates

place the half-life of an engineering degree at between 2.5 and 5 years, requiring between 10 and 20 hours of study per week. Welcome to the treadmill, where you have to run faster and faster so that you don't fall behind. Unsurprisingly, putting in this kind of time is simply impossible for most people. The result is an ever-shrinking length of a typical engineer's career and a bias towards hiring recent graduates. A partial escape from this time-consuming treadmill that offers little progress is to recognize the continuous need for learning. If you agree with that, it becomes easier to place time and emphasis on developing heuristics and systems to foster learning. The faster the pace of knowledge change, the more valuable the skill of learning becomes. A study by PayScale found that the median age of workers in most successful technology companies is substantially lower than that of other industries. Of 32 companies, just six had a median worker age above 35, despite the average across all workers being just over 42. Eight of the top companies had a median worker age of 30 or below — 28 for Facebook, 29 for Google, and 26 for Epic Games. The upshot is that salaries are high for those who can stay current while gaining years of experience. In a similar vein, business models have ever shrinking half-lives. The nature of capitalism is that you have to be better last year than you were this year — not to gain market share but to maintain what you already have. If you want to get ahead, you need asymmetry; otherwise, you get lost in trench warfare. How long would it take for half of Uber or Facebook's business models to be irrelevant? It's hard to imagine it being more than a couple of years or even months. In *The Business Model Innovation Factory: How to Stay Relevant When the World Is Changing*, Saul Kaplan highlights the changing half-lives of business models. In the past, models could last for generations. The majority of CEOs oversaw a single business for their entire careers. Business schools taught little about agility or pivoting. Kaplan writes: During the industrial era once the basic rules for how a company creates, delivers, and captures value were established[,] they became etched in stone, fortified by functional silos, and sustained by reinforcing company cultures. All of a company's DNA, energy, and resources were focused on scaling the business model and beating back competition attempting to do a better job executing the same business model. Companies with nearly identical business models slugged

it out for market share within well-defined industry sectors. Those days are over. The industrial era is not coming back. The half-life of a business model is declining. Business models just don't last as long as they used to. In the twenty-first century business leaders are unlikely to manage a single business for an entire career. Business leaders are unlikely to hand down their businesses to the next generation of leaders with the same business model they inherited from the generation before.

VI. The Burden of Knowledge-The flip side of a half-life is the time it takes to double something. A useful guideline to calculate the time it takes for something to double is to divide 70 by the rate of growth. This formula isn't perfect, but it gives a good indication. Known as the Rule of 70, it applies only to exponential growth when the relative growth rate remains consistent, such as with compound interest. The higher the rate of growth, the shorter the doubling time. For example, if the population of a city is increasing by 2 percent per year, we divide 70 by 2 to get a doubling time of 35 years. The rule of 70 is a useful heuristic; population growth of 2 percent might seem low, but your perspective might change when you consider that the city's population could double in just 35 years. The Rule of 70 can also be used to calculate the time for an investment to double in value; for example, \$100 at 7 percent compound interest will double in just a decade and quadruple in 20 years. The average newborn baby doubles its birth weight in under four months. The average doubling time for a tumor is also four months. We can see how information changes in the figures for how long it takes for a body of knowledge to double in size. The figures quoted by Arbesman (drawn from *Little Science, Big Science ... and Beyond* by Derek J. de Solla Price) are compelling, including:also gives figures for the time taken for the available knowledge in a particular field to double, including:The doubling of knowledge increases the learning load over time. As a body of knowledge doubles so does the cost of wrapping your head around what we already know. This cost is the burden of knowledge. To be the best in a general field today requires that you know more than the person who was the best only 20 years ago. Not only do you have to be better to be the best, but you also have to be better just to stay in the game. The corollary is that because there is so much to know, we

specialize in very niche areas. This makes it easier to grasp the existing body of facts, keep up to date on changes, and rise to the level of expert. The problem is that specializing also makes it easier to see the world through the narrow focus of your specialty, makes it harder to work with other people (as niches are often dominated by jargon), and makes you prone to overvalue the new and novel.

Step 75 - Power of I do not know

1. It's ok to say I don't know.
2. Just because you vomit out an opinion on something doesn't make it so. Too often we fail to consider that maybe what we're reading or writing is wrong. We're scared to say I don't know.
3. Do Not Have the Opinion and do not make any judgement about Anything, I see and hear, If I did not work Hard to have an opinion. I need to Read, Analyse, Research the topic from every angle, so that I can have an opinion or Make Judgement on the topic.

Step 76-Application From The Book

Record Application

A. Read or listen 25min and 5min break.

- Read or Listen 20 pages an Hour according Mortimer Adler.

B. Read or Listen following Tools to Use Application.

1. Folder Application+ Introduction to Hermeneutics Chapter 12.
2. Speed of Tool Books:Analysing audiobook listen between 75 words per minute to 285 words per minute or listen between 0.5-1.9 times speed to Find Application.

C. Speed of Audiobook.

- Analysing audiobook listen between 75 words per minute to 285 words per minute or listen between 0.5-1.9 times speed to **Use Application.**

D. Depending on which topics you have chosen, the best way to integrate them is to try and find points of convergence (meet).

E. **Review application side rules of reading, how would I respond and what does it mean to you. Ask myself if I done the analysis of each part of how to rules of reading and how can I apply these ideas to my life that it is most accurately.**

F. Six Stages of learning transfers:

- Non Specific transfer-Everything we learn is acquired as result of what we have learned in past.
- Application transfer-involves applying the knowledge.
- Context Transfer-involves use of your knowledge for situation that is slightly different from the one in which you initially acquired it. Example non- academic writing requires linguistic skills that are somewhat different and persisting with formal language.
- Near Transfer-continue to apply your acquired knowledge in situation that are similar to the one where you were originally exposed to it. Example car with manual transmission use the knowledge to use truck with manual transmission.
- Far Transfer-test your ability to take a piece of learned knowledge and apply it in some context that is entirely dissimilar to the one where you acquired.
- Displacement or creative transfer-takes the integrative skills we acquired in previous step to the next level. Example: you jump in the air and feel yourself being pulled down due to gravitational force. Later you enter an elevator and feel yourself accelerated upwards at similar rate as the one that pulled you down while jumping.

If you connect the dots, the upward acceleration from lift and the downward pull of gravity are actually the same thing. Ask yourself questions.

- Does this subject connect well to another domain of knowledge that related or unrelated?
- Where else have I come across this idea?
- How difficult was it for me to grasp this?
- Can I break down into smaller parts?
- How would I explain this to a child?
- Why is this important to know?
- What questions does this raise for me?
- What, if anything surprises me about this?

G. Use 5W and 1H

1. Who?
2. What?
3. When?
4. Where?
5. Why?
6. How?
7. So What?

H. What does the writer wants me to learn?

1. Philosophy.
2. Motivation.
3. Finance.
4. Economics.
5. Philosophy.
6. Linguistics.
7. Language.
8. Logic.
9. Reasoning.
10. Morality.
11. Ethics.
12. Dilemmas.
13. Liberty.

14. Freedom.
15. Freedom of speech.
16. Archeology.
17. Religion.
18. Humanity.
19. Human condition.
20. God.
21. Human behaviour.
22. Values.
23. Challenges.
24. beliefs.
25. Atheism.
26. Beauty and etc.
27. Any Other Values, Roles, Behavior or anything else.

I. How to I know that this idea applicable in reality?

1. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. The problem is we often think the world *should* work differently than it does. The word “should” is important. Because we think the world should work in a way that it doesn’t, our approach is suboptimal.
2. Part of the answer is we don’t listen to the feedback of reality. When we don’t get the outcome we’re seeking, the last place we look is with our actions. It’s too easy to wiggle out of responsibility by blaming others and circumstances. It’s not that this approach is entirely ineffective. We eventually get the job half done in twice the time. The person working with the world, however, gets the job fully done in half the time.
3. The most common source of feedback is people not reality. One problem with feedback from people is that it’s hard to give someone else high quality feedback. Think about it. People will tell you a few helpful things but they’ll often avoid the big thing that’s holding you back. They don’t want to hurt your feelings. They want you to like them. That’s not the biggest problem. The biggest problem is that people rarely know much more than you do. If they had all the answers, they’d get better results.

4. Another form of people feedback comes from groups, institutions, and society. This is the way things have been done. And while there might be good reason for doing things the same way they've always been done, if you take your feedback from these folks, you'll incrementally improve what's already exists rather than use first principles to design something new. If exiting institutions knew what they were doing, we wouldn't have startups or bankruptcy lawyers.
5. How do we identify how the world really works? Outcome over ego. You are accountable for your outcomes. When you take responsibility for your outcomes you get feedback from reality. When you get feedback from reality, you adjust your behaviour.

J. Applying Lessons from the Past

1. Review History Written by Losers as well, this helps to review and see big picture of the world.
2. "History is written by the winners" is the popular view. But your winner may not be my winner. A lot depends on the narrative you are trying to build.
3. History is rewritten all the time. Sometimes it is rewritten because new information has come to light, perhaps from an archeological find or previously classified documents. When this happens, it is exciting. We joyfully anticipate that more information will deepen our understanding. But rewriting frequently happens in the service of building a cultural or national narrative. We highlight bits of the past that support our perceived identities and willfully ignore the details that don't fit. We like our history uncomplicated. It's hard for us to understand our groups or our countries, and by extension ourselves, as both good and not-good at the same time.
4. Culture is a collective memory. It's the interwoven stories that we use to explain who we are as nations, organizations, or just loosely formed groups. "Collective memory is more about the present than the past because it is integral to how the group sees itself." And "while collective memory is usually grounded in fact, it need not be."
5. We have seen how people justify all kinds of mistakes to preserve the personal narratives they are invested in, and groups also engage in this behavior. Countries rewrite their histories, from the textbook up, to support how they see themselves now. Instinctively we may recoil from this idea, believing that it's better to turn over all the rocks and confront what is lurking underneath. However,

as MacMillan writes, “It can be dangerous to question the stories people tell about themselves because so much of our identity is both shaped by and bound up with our history. That is why dealing with the past, in deciding on which version we want, or on what we want to remember and to forget, can become so politically charged.”

6. MacMillan warns that the danger of abusing history is that it “flattens out the complexity of human experience and leaves no room for different interpretations of the past.” Which leaves us asking, What do we want from history? Do we want to learn from it, with the hopes that in doing so we will avoid mistakes by understanding the experiences of others? Or do we want to practice self-justification on a national level, reinforcing what we already believe about ourselves to justify what we did and what we are doing? After all, “you could almost always find a basis for your claims in the past if you looked hard enough.”
7. If we selectively use the past only to reinforce our claims in the present, then the situation becomes precarious when there is pressure to change. Instead of looking as objectively as possible at history, welcoming historians who challenge us, we succumb to confirmation bias, allowing only those interpretations that are consistent with the narrative we are invested in. Consider what MacMillan writes about nationalism, which “is a very late development indeed in terms of human history.”
8. When we selectively reach back into the past to justify claims in the present, we reduce the complexity of history and of humanity. This puts us in an awkward position because the situations we are confronted with are inherently complex. If we cut ourselves off from the full scope of history because it makes us uncomfortable, or doesn’t fit with the cultural narrative in which we live, we reduce our ability to learn from the past and apply those lessons to the situations we are facing today. MacMillan says, “There are also many lessons and much advice offered by history, and it is easy to pick and choose what you want. The past can be used for almost anything you want to do in the present. We abuse it when we create lies about the past or write histories that show only one perspective. We can draw our lessons carefully or badly. That does not mean we should not look to history for understanding, support and help; it does mean that we should do so with care.”
9. We need to accept that people can do great things while still having flaws. Our heroes don’t have to be perfect, and we can learn just as much from their

imperfections as from their achievements. We have to allow that there are at least two sides to every story, and we have to be willing to listen to both. There are no conflicts in which one side doesn't feel morally justified in their actions; that's why your terrorist can be my freedom fighter. History can be an important part of bridging this divide only if we are willing to lift up all the rocks and shine our lights on what is lurking underneath.

10. Be informed citizen is read more classical books and history. This unfolds how the real world works and where it is going. If You read Classical Books, then you can well predict what would happen next in the future based on the events happening.

K. How can this idea be applied in real life?

L. Has this idea stood the test of time?

M. What steps do I need to take to apply this idea in reality?

1. We have to contextualise the knowledge. When does it work?
2. When doesn't it work? Where can I apply it?
3. What are the key variables?

N. In what area of life this idea applicable?

O. Is this idea still applicable in present time?

P. What does this idea improves in my life?

Q. What of it?

R. What follows?

S. What difference does it make?

T. What was my favourite part of the book? Why?

U. Who was the favourite character? Why?

V. What was the most interesting thing I learned from the book?

W. Would I have ended the book differently? Did it end the way I thought it would?

X. If I could change one thing in the book, what would it be?

Y. Do I know example of someone who is like one of the characters in the story?

Z. If I could have conversation with one of the characters in the story, which character would I choose and what I talk about it?

AA. What am I believe?

BB. How will I reveal my faith and my knowledge through my actions?

CC. What I understood about Jesus, Father and Holy Spirit from the Bible? And what I understood about other things from the books?

DD.How that encourage me?

EE.What I could learn from this?

FF. Do I find bad/good examples from the books?

GG.Do I find any commandment that I must obey?

HH.Do I find any warnings?

II. Do I find any promise?

JJ. Do I find the sin that I have to repent?

KK.What truths God have revealed to me?

LL. What truths about others have revealed to me?

MM.How can I do practically?

NN.What the main thought do I have to remember?

OO.How can I show my life fruit, character, love, faith and maturity in my daily life?

PP.How do I have desire to be discipline character in fruit, faith that he is ejected to authorised and filled with Christ?

QQ.What a thing is blocking me from God's work?

RR.How can I contribute with God work and discipline my self to complete the work?

SS.What can I do that God's work will be functional and better and stronger and faster even then. When I have doubt, uncertainty and stress?

TT. What can I do practical?

UU.What example can I be? To learn and teach others?

VV.Question that I do not understand in the paragraph?

WW.Don't Overheard Complaining, not even to yourself. If you have fewer Opinion, if you just accept things as they are, you have less to complain about

XX.So step by step action by action, no-one can stop you from that. Focus on the part of the things that is up to you, and trust , if you follow the process that more times than not, you will get the outcome you want.

YY.Worst Enemy of The Person is her his own Tongue, as the person will always boast or Talk out their ideas and thoughts. Always observe the person, as the person will always boast about their ideas, winning and thoughts, and do not interrupt the person. Bible tells about tongue in James 3: It corrupts the whole person, sets the whole course of his life on fire, and is itself set on fire by hell. but no man can tame the tongue. It is a restless evil, full of deadly poison. With the tongue we praise our Lord and Father, and with it we curse men, who have been made in God's likeness.

ZZ.How To Put Ideas into Practice. How The Idea can be put into practice.

AAA.Do not watch what they talking, but watch what they are doing, to determine what type of person she/he is.

BBB.We needs to work on the things that we not good at, and not just things that we are strong at. This would make you better as whole.

CCC.If the Product is for Free, then You are the Product for the company.

DDD.There is no free Lunch, if somebody offers something for free, then there is something behind that offer.

EEE.Always remember Nobody is going to come to rescue and your family and do not put faith into politicians and other people as they are humans and put all the trust into God.

How Will I Add This Information In My Own Life.

How Will I Apply This Information In My Life.

Step 77-Application Mental Models To the Real Life

1. Understand Mental Models

Start by familiarising yourself with various mental models. Mental models are frameworks for understanding how the world works. They help you interpret information, make decisions, and solve problems.

Some common mental models include first principles thinking, Occam's Razor, second-order thinking, probabilistic thinking, inversion, and the map-territory distinction.

0. All Models Are Wrong

All Models Are Wrong

Closely related to the map-territory relation, it's an aphorism in statistics commonly stating: All models are wrong, but some are useful. Attributed to statistician George Box, the thinking is considered applicable to all scientific models.

Primary source: George Box

How is your journey towards understanding Farnam Street's [latticework of mental models](#) going? Is it proving useful? Changing your view of the world? If the answer is that it's going well that's good. There's just one tiny hitch.

All models are wrong.

Yep. It's the truth. However, there is another part to that statement:

All models are wrong; some are useful.

Those words come from the British statistician, [George Box](#). In a groundbreaking 1976 paper, Box revealed the fallacy of our desire to categorize and organize the world. We create models (a term with many applications), once to confuse them for reality.

Box also stated:

Remember that all models are wrong; the practical question is how wrong do they have to be to not be useful.

What Exactly Is A Model?

First, we should understand precisely what a model is.

The dictionary definition states a model is 'a representation, generally in miniature, to show the construction or appearance of something' or 'a simplified description, especially a mathematical one, of a system or process, to assist calculations and predictions.'

For our purposes here, we are better served by the second definition. A model is a simplification which fosters understanding.

Think of an architectural model. These are typically a small scale model of a building, made before it's built. Its purpose is to show what the building will look like and to help

people working on the project to develop a clear picture of the overall feel. In the iconic scene from Zoolander, Derek (played by Ben Stiller) looks at the architectural model of his proposed 'school for kids who can't read good' and shouts "What is this? A center for ants??"

That scene illustrates the wrong way to understand models: Too literally.

Why We Use Models- And Why They Work

At Farnam Street, we believe in using models for the purpose of building a massive, but finite amount of fundamental, invariant knowledge about how the world really works.

Applying this knowledge is the key to making good decisions and avoiding stupidity.

"Scientists generally agree that no theory is 100 percent correct. Thus, the real test of knowledge is not truth, but utility. Science gives us power. The more useful that power, the better the science."

— Yuval Noah Harari

Time-tested models allow us to understand how things work in the real world. And understanding how things work prepares us to make better decisions without expending too much mental energy in the process.

Instead of relying on fickle and specialized facts, we can learn versatile concepts.

The mental models we cover are intended to be widely applicable.

It's crucial for us to understand as many mental models as possible. As the adage goes, a little knowledge can be dangerous and creates more problems than total ignorance. No single model is universally applicable – we find exceptions for nearly everything. Even hardcore physics has not been totally solved.

"The basic trouble, you see, is that people think that "right" and "wrong" are absolute; that everything that isn't perfectly and completely right is totally and equally wrong."

— Isaac Asimov

Take a look at almost any comment section on the internet and you are guaranteed to find at least one pedant raging about a minor perceived inaccuracy, throwing out the good with the bad. While ignorance and misinformation are certainly not laudable, neither is an obsession with perfection.

Like heuristics, models work as a consequence of the fact they are usually helpful in most situations, not because they are always helpful in a small number of situations.

Models can assist us in making predictions and forecasting the future. Forecasts are never guaranteed, yet they provide us with a degree of preparedness and comprehension of the future. For example, a weather forecast which claims it will rain today may get that wrong. Still, it's correct often enough to enable us to plan appropriately and bring an umbrella.

Mental Models and Minimum Viable Products

Think of mental models as minimum viable products.

Sure, all of them can be improved. But the only way that can happen is if we try them out, educate ourselves and collectively refine them.

We can apply one of our mental models, Occam's razor, to this. Occam's razor states that the simplest solution is usually correct. In the same way, our simplest mental models tend to be the most useful. This is because there is minimal room for errors and misapplication.

"The world doesn't have the luxury of waiting for complete answers before it takes action."

— Daniel Gilbert

Your kitchen knives are not as sharp as they could be. Does that matter as long as they still cut vegetables? Your bed is not as comfortable as it could be. Does that matter if you can still get a good night's sleep in it? Your internet is not as fast as it could be. Does that

matter as long as you can load this article? Arguably not. Our world runs on the functional, not the perfect. This is what a mental model is – a functional tool. A tool which maybe could be a bit sharper or easier to use, but still does the job.

The statistician David Hand made the following statement in 2014;

In general, when building statistical models, we must not forget that the aim is to understand something about the real world. Or predict, choose an action, make a decision, summarize evidence, and so on, but always about the real world, not an abstract mathematical world: our models are not the reality.

For example, in 1960, Georg Rasch said the following:

When you construct a model you leave out all the details which you, with the knowledge at your disposal, consider inessential.... Models should not be true, but it is important that they are applicable, and whether they are applicable for any given purpose must, of course, be investigated. This also means that a model is never accepted finally, only on trial.

Imagine a world where physics like precision is prized over usefulness.

We would lack medical care because a medicine or procedure can never be perfect. In a world like this, we would possess little scientific knowledge, because research can never be 100% accurate. We would have no art because a work can never be completed. We would have no technology because there are always little flaws which can be ironed out.

“A model is a simplification or approximation of reality and hence will not reflect all of reality ... While a model can never be “truth,” a model might be ranked from very useful, to useful, to somewhat useful to, finally, essentially useless.”

— Ken Burnham and David Anderson

In short, we would have nothing. Everything around us is imperfect and uncertain. Some things are more imperfect than others, but issues are always there. Over time, incremental improvements happen through unending experimentation and research.

The Map is Not the Territory

As we know, the map is not the territory. A map can be seen as a symbol or index of a place, not an icon.

When we look at a map of Paris, we know it is a representation of the actual city. There are bound to be flaws; streets which have been renamed, demolished buildings, perhaps a new Metro line. Even so, the map will help us find our way. It is far more useful to have a map showing the way from Notre Dame to Gare du Nord (a tool) than to know how many meters they are apart (a piece of trivia.)

Someone who has spent a lot of time studying a map will be able to use it with greater ease, just like a mental model. Someone who lives in Paris will find the map easier to understand than a tourist, just as someone who uses a mental model in their day to day life will apply it better than a novice. As long as there are no major errors, we can consider the map useful, even if it is by no means a reflection of reality. Gregory Bateson writes in Steps to an Ecology of Mind that the purpose of a map is not to be true, but to have a structure which represents truth within the current context.

“A map is not the territory it represents, but, if correct, it has a similar structure to the territory, which accounts for its usefulness.”

— Alfred Korzybski

Physical maps generally become more accurate as time passes. Not long ago, they often included countries which didn't exist, omitted some which did, portrayed the world as flat or fudged distances. Nowadays, our maps have come a long way.

The same goes for mental models – they are always evolving, being revised – never really achieving perfection. Certainly, over time, the best models are revised only slightly, but we must never consider our knowledge “set”.

Another factor to consider in using models is to take into account what they’re used for. Many mental models (e.g. entropy, critical mass and activation energy) are based upon scientific and mathematical concepts. A person who works in those areas will obviously need a deeper understanding of it than someone who want to learn to think better when making investment decisions. They will need a different map and a more detailed one showing elements which the rest of us have no need for.

“A model which took account of all the variation of reality would be of no more use than a map at the scale of one to one.”

— Joan Robinson

In his essay *Partial Enchantments of the Quixote*, Jorge Luis Borges provides an even more interesting analysis of the confusion between models and reality:

Let us imagine that a portion of the soil of England has been leveled off perfectly and that on it a cartographer traces a map of England. The job is perfect; there is no detail of the soil of England, no matter how minute that is not registered on the map; everything has there its correspondence. This map, in such a case, should contain a map of the map, which should contain a map of the map of the map, and so on to infinity. Why does it disturb us that the map be included in the map and the thousand and one nights in the book of the Thousand and One Nights? Why does it disturb us that Don Quixote be a reader of the Quixote and Hamlet a spectator of Hamlet? I believe I have found the reason: these inversions suggest that if the characters of a fictional work can be readers or spectators, we, its readers or spectators, can be fictions.

How Do We Know If A Model Is Useful?

This is a tricky question to answer. When looking at any model, it is helpful to ask some of the following questions:

- How long has this model been around? As a general rule, mental models which have been around for a long time (such as Occam’s razor) will have been subjected to a great deal of scrutiny. Time is an excellent curator, trimming away inefficient ideas. A mental model which is new may not be particularly refined or versatile. Many of our mental models originate from Ancient Greece and Rome, meaning they have to be functional to have survived this long.
- Is it a representation of reality? In other words, does it reflect the real world? Or is it based on abstractions?
- Does this model apply to multiple areas? The more elastic a model is, the more valuable it is to learn about. (Of course, be careful not to apply the model where it doesn’t belong. Mind Feynman: “You must not fool yourself, and you’re the easiest person to fool.”)
- How did this model originate? Many mental models arise from scientific or mathematical concepts. The more fundamental the domain, the more likely the model is to be true and lasting.
- Is it based on first principles? A first principle is a foundational concept which cannot be deduced from any other concept and must be known.
- Does it require infinite regress? Infinite regress refers to something which is justified by principles, which themselves require justification by other principles. A model

based on infinite regress is likely to require extensive knowledge of a particular topic, and have minimal real-world application.

When using any mental model, we must avoid becoming too rigid. There are exceptions to all of them, and situations in which they are not applicable.

Think of the latticework as a toolkit. That's why it pays to do the work up front to put so many of them in your toolbox at a deep, deep level. If you only have one or two, you're likely to attempt to use them in places that don't make sense. If you've absorbed them only lightly, you will not be able to use them when the time is at hand.

If on the other hand, you have a toolbox full of them and they're sunk in deep, you're more likely to pull out the best ones for the job exactly when they are needed.

Too many people are caught up wasting time on physics-like precision in areas of practical life that do not have such precision available. A better approach is to ask "Is it useful?" and, if yes, "To what extent?"

Mental models are a way of thinking about the world that prepares us to make good decisions in the first place.

0a. What is the mental model.

Mental model is representation of how the world works. We operate in a very complex world, and it is hard to understand all the variables of the world. We use different types of ideas and models that we do understand to aid us to learn about the things we do not understand and the way the world works. You learn fundamental concepts of other disciplines to help you to get a bigger picture of the world and also a toolbox to see the world through. The more models you have, the more lenses you can use while you look at the world, the fewer blind spots you can have.

In other words, mental models are nothing more than pre-design frameworks, that you can pull out, whenever a situation requires a decision, you just plug different variables and out pops an answer. This is a systematized process of good judgement. Once you regularly tapping into these frameworks, the quality of my decision developed in life and other things you do.

How to Apply mental models

How to use mental models

If all you have is a hammer, everything looks like a nail. A common misconception is that mental models should be dutifully practiced and applied in order to improve your mental performance. There are actually many mental models which you should work hard to *avoid*. For example, having an "illusion of control" can be particularly dangerous in some situations.

In order to grow as a human being, you need to be able to *identify* mental models, whether you are using them, or the person you are talking to is. Ideally, you need to make it a conscious choice to use them or not, instead of falling prey to the automatic thinking our brain loves so dearly.

“To break a mental model is harder than splitting the atom.”

Albert Einstein (but probably not)

So how can you challenge your mental models, identify them in others, and use them in a way that is actually effective and beneficial?

Here are a few tips you can apply to master mental models, rather than being enslaved by them.

- Be aware of your thinking by asking yourself provoking questions
- Gather information to challenge your thinking with actual facts
- Inquire into other people’s thinking and challenge their views
- Resist jumping to conclusions and suspend your assumptions
- Look for recurring thought patterns and unlearn them

A tool is only as good as its user. Only once you're aware of your mental models, you can use them effectively to achieve your goals.

How to build your own mental models

In a fast-moving environment, mental models can be extremely useful to help you think fast and make decisions. After all, they're great at giving you rules of thumb so you can, if done well, predict likely outcomes or behaviours.

- **Observe people.** One great way to develop your own mental models is to find inspiration in people. When you read a biography, ask yourself: why did they make this decision? What were they thinking? What mental model(s) did they use? It doesn't have to be famous entrepreneurs or creatives. We all have a friend or a colleague whose work we admire. When you see them make a specific choice in a complex situation, ask them how they came to that decision.
- **Take note of nature.** Nature follows many rules that can apply to human decision making. For example, the tendency to minimise our energy output can be observed in many natural conditions, and incentives are a key drive in all creatures' behaviour.
- **Ask for feedback.** Ask a friend or a colleague to observe how you act and to help you identify behaviours that may not be obvious to you. This can be an incredibly uncomfortable but mind-expanding exercise.

Don't limit yourself to constructive mental models. You will observe mental models which you'd rather *not* reproduce. These are great to study as well, because it's easier to avoid a thought pattern when you know how to spot it in yourself and others. Constructive or destructive, name your mental models and write them down.

Why Are Mental Models Important To Understand?

In our heads, we carry models of how the world works.

Scientists label mental models as, "cognitive representations of external reality."

Let's return to the clouds for a moment to visualize this a bit better.

You see a cloud in the sky. And while your eyes see a cushy shape. Your brain turns this shape into something meaningful – an animal, or the face of the friendly superhero, Spider-Man, for example.

But is the cloud actually trying to imitate the shape of an animal, or is just your mind playing tricks?

Of course, it's the latter.

If you ask another person. He'll either see just a cloud or imagine something completely different.

Why?

Because he has a different set of mental models in his head.

And while looking at clouds and imagining superheroes is not dangerous.

What do you think will happen if you misinterpret an outside event while investing in stocks?

You lose money.

What do you think will happen if you misinterpret an email from a colleague?

It might lead to a pointless argument or not doing your job right.

But there is more...

A common thing we all do is be a victim of our biases.²

For example, by looking at people who made it in a particular field, we convince ourselves that we'll make it, too.

Also known as the survivorship bias. Brands are constantly using this to persuade us to buy courses, products, Notion templates (like we don't have enough already), etc.

Consider this for a moment... When you go to a website that sells Ebook Readers, for example. The page showcase only the positive reviews. All the benefits of using the device. Of course, nothing negative is mentioned. That's why we start to believe that we'll also improve our reading experience if we purchase this fancy tool.

But is it really that helpful?

It might be. But that's not guaranteed.

As it is not guaranteed that starting a business will result in a successful business. Starting a business and a successful business are two quite different things.

Of course, we start one hoping to eventually become successful but hope, alone, won't make it profitable.

Understanding that what we think. What we form in our heads is not reality can save you from embarrassing dialogue, making financially unstable decisions, and all kinds of other inadequate conclusions.

How Mental Models Are Formed?

Mental models are formed in our heads as we experience life. The more we expose ourselves to different events, the more mental models we are able to form.

However, as knowledge fades over time. We only keep the ones that are frequently used. Still, this doesn't stop us from drawing conclusions even if we spot unfamiliar things.

Here's an example: When we are young and we see something for the first time. We will draw conclusions from what is familiar to describe the unfamiliar.

That's why children will label tigers, pumas, cougars, leopards simply as cats. They don't know that these are different – they still don't have the extra lenses. But relying on what they know, they make conclusions to make sense of the world.

These are innocent mistakes.

But again, when we grow up. We can't afford to make such misjudgments. We need to form a latticework of mental models that will help us both avoid errors and consistently make good decisions.

How Mental Models Unlock Your Thinking

Ok, what do we know so far?

We know that mental models are the way we make sense of reality. But we also know that they can be flawed.

Since you can't go to the store and purchase a floppy disk containing the best thinking types used by all the astonishingly rich people of our time and insert it into your ordinary brain – like in the movie The Matrix when Neo learned jiu-jitsu in 10 minutes.

You need to do the hard work of creating a set of thinking concepts in your head while also considering the fact that some of the current ways you think are probably dangerous and need revision.

The question then becomes: "How can I ensure that what I see, and therefore believe, is not incorrect? And, how I can acquire a nice set of mental models that will help me make better decisions and also avoid misinterpretation?"

Charlie Munger, the person who popularized the use of multi-disciplinary mental models says the following:³

“As I said at the U.S.C. Business School, what you need is a latticework of mental models in your head. And you hang your actual experience and your vicarious experience (that you get from reading and so forth) on this latticework of powerful models. And, with that system, things gradually get to fit together in a way that enhances cognition. And you need the models – not just from one or two disciplines, but from all the important disciplines. You need the best 100 or so models from microeconomics, physiology, psychology particularly, elementary mathematics, hard science and engineering [and so on].” Charlie Munger

So, you can’t expect to improve your thinking when you study one area. You need to study *all* the important areas to bump up the IQ of your brain.

Shane Parrish, the person who founded the blog [Farnam Street](#) – the go-to place for mental models. Explains this as creating a mental toolbox for your brain. To visualize this better. I’m going to use the most cited quote about mental models, “If all you have is a hammer, everything looks like a nail.”

Obviously, you can’t bang everything with a hammer. We constantly encounter events that require a bit more grace.

So, how can you acquire a nice set of ways to think?

Extremely easy to say, but crazily hard to practice – you learn them.

Creating a Latticework of Mental Models

Mental models are kind of like keyboard shortcuts.

At the right time, you press a combo of keys and you perform a task faster.

Can you do a task without the shortcut? Yes. Is it more efficient? No.

But there is more.

As people who are obsessed with finding new keyword combinations. Knowing more keys helps you besides navigating around dozens of browsers. It clears the fog around what is possible.

Knowing more helps you see how more things are possible.

It removes the brick wall around your average brain.

Or in other words, expert developers see meaning in code while other people see gibberish.

How to learn more ways to think faster and better?

Two ways:

1. Experience more.
2. Learn more.

The first one doesn't guarantee that you will improve your thinking. Plus, it's a slower process.

If you work the same job for 20 years, this doesn't mean that you will master it. Usually, your performance will start to regress if you do the same things without pushing yourself outside your comfort zone.

The solution then, is to learn more techniques. Master what other people have already figured out.

Instead of throwing 100 mental models at you and hoping you will catch some. For the past couple of months, I was busy discovering and packaging the most important thinking concepts into categories.

How to Use Mental Models

Above I mentioned that mental models are like tools inside a toolbox. The difference is that instead of objects, you have thinking concepts.

Personally, I prefer lenses instead of tools. Lenses that sit somewhere in our brain and distort reality based on the set of lenses we have.

Here's a more vivid example:

Since we experience life by observing what happens to us. When you see something, feel something. That event is immediately analyzed by our mental models. They are our first line of defense. And based on our thinking concept. We behave in a certain way.

When you have a limited set of mental models, you will act always the same way regardless of the situation.

From there, since you can't change what happens to you. You will probably conclude that you should change your behavior. But that's not quite right.

Mental models filter the incoming information and assign tasks to the body – what the body should do. So, what you really need is to change your mental models, add new ones, and consider all possible scenarios based on the different thinking concepts. And more importantly, give yourself more time to think.

Not only because waiting will calm you down and prevent you from making an emotional decision instead of a rational one. But also because you will have more time to see the problem from different lenses and decide which behavior will lead to the most appropriate outcome.

When you have a wide set of mental tools. You can think about the different consequences when you choose something. Then, pick the best way to act depending on the situation.

When your portfolio of thinking concepts is bigger, you will have the ability to see different outcomes when different lenses are applied. Thus, make the best decision.

Here's a "real-life" example:

A friend introduces you to a new way to make money. A company that offers website-building services and uses AI to generate content. Given that the content is generated automatically. You do nothing. You simply pay a monthly fee and wait for results.

The process is presented as seamless. You go through an initial setup and then just see how articles are added and money is printed. The reviews on the website seem like everybody is making a good amount of money. So, you decide to join.

In this simple example, we can identify three mental patterns that convince us that we should join the platform:

- **Conformity:** Since the program was recommended by a friend, you are more likely to believe it.
- **Survivorship bias:** The positive reviews convince us that success is guaranteed. However, we see only the people who made it. We don't know how many people tried and failed.
- **Hyperbolic discounting:** We are designed to want immediate rewards over rewards that come later. It's one thing to start a website and earn money after a year – what actually happens. It's quite another to start a website and start earning today – what the website we are observing is trying to convince us.

If we think about it, however. And if we expand our set of lenses. We can spot errors in the service recommended by the friend:

- **Incentive:** What is the real incentive of the person? He can be sharing an affiliate link. Or, he can have a track record of a person who is always looking for quick-rich schemes.
- **The map is not the territory:** All websites that sell something present their services are super easy to use. However, maps are not reality. That's why, when we chew on it, we will find out that we can't expect a site that offers an easy way to make money to actually be easy.
- **Second-order thinking:** When we consider the consequences of our decision. We will probably find a couple of facts that will save us the agony of signing up for this imaginary service: Google doesn't like computer-generated income; Sites that offer easy money never deliver.

So, here's an easy framework that you can follow when you have to make a decision:

How to use mental models:

- Pause. Don't react immediately.
- Note down your initial decision.
- Gather additional information if needed.
- Observe the situation using different mental models.
- Challenge your assumptions.
- Try to estimate the likelihood of the different options.
- Imagine the worst that can happen.

One extra thing to be aware of is that you are your biggest enemy.

Since the whole process happens in your head – there is no one to give you feedback. It's of great importance to observe the situation objectively. If possible, ask someone for advice. This other person will surely give you a new way to think about the situation because his set of lenses is different.

How to Build Your Own Mental Models

There are plenty of [books on mental models](#). Quite a few blog posts that talk about them. And passionate online discussion about them, too.

You might think that all the mental models are already invented and documented. That's not the case.

You can create your own that best fit your conditions.

Like you can create shortcuts on your keyboard. You can also create your own thinking tools.

How to Create a Mental Model

Here's what you can do:

- **Observe your life:** Think about what type of decisions you are regularly facing. How do you usually respond? Why?
- **Observe the life of others:** Given the above. See how others respond in similar situations. What do they do differently? How do they act? And more importantly, how do they think? Since mental models are ways to think, questioning people to understand how they think when they face problems will give you important insights.
- **Pause, act, revise:** After the above two, you will have a better idea of how to respond to a particular situation. Once we have a new framework. The first thing we need to do is to pause – this prevents us from acting like we normally do. Then, act based on our new mental model. Finally, revise our thinking concept and make adjustments along the way.

Some Closing Thoughts

I see a lot of people talking about mental models but do little with them.

It's not that we have a problem with access to the best mental models. We have a problem with adopting them.

When we read about mental models we say, "Oh, that's good stuff!" But when we actually need to make a decision. We do what we normally do.

Our brain is cemented to our old beliefs and behavior.

The solution?

Increase the time you need to make a decision. Invite slow thinking (start with practicing slow reading and conducting a beliefs audit) and improve your fast thinking.

You need to prevent your initial statement to be your actual statement. Give yourself some time to invite the lenses – mental models – you have adopted while browsing online in your working memory.

Always think about the side effects.

And, as Peter Bevelin writes in Seeking Wisdom, "One way to reduce unintended consequences is to stop focusing on isolated factors and instead consider how our actions affect the whole system."

All of the above, I hope, will aid you in your quest to improve your thinking. Because improving your thinking is the first step towards improving all the areas in our lives.

2. Identify Relevant Disciplines.

Determine which disciplines are relevant to the problem or situation you're addressing.

This could include fields like psychology, economics, biology, engineering, sociology, and more.

Each discipline offers unique perspectives and methodologies that can enrich your understanding and analysis.

3. Analyse the Problem

Clearly define the problem you're trying to solve or the situation you're trying to understand.

Break down the problem into its constituent parts and consider how each part relates to different disciplines.

4. Understand how the world works.

The world is a complex system governed by various interconnected factors, including natural laws, human behavior, social structures, economic systems, political institutions, cultural dynamics, and technological advancements. Here's a simplified breakdown:

1. **Natural Laws:** The physical world operates according to fundamental principles such as gravity, thermodynamics, electromagnetism, and quantum mechanics. These laws govern everything from the movement of celestial bodies to the behavior of atoms.
2. **Human Behavior:** Human actions and interactions are influenced by a combination of biological, psychological, and social factors. Understanding human behavior involves disciplines such as psychology, sociology, anthropology, and economics.
3. **Social Structures:** Societies are organized into various structures such as families, communities, institutions, and governments. These structures shape norms, values, roles, and power dynamics within society.
4. **Economic Systems:** Economies determine how goods and services are produced, distributed, and consumed within a society. Different economic systems, such as capitalism, socialism, and mixed economies, prioritize different principles and values.
5. **Political Institutions:** Governments and political systems establish laws, regulations, policies, and governance structures that influence the distribution of power and resources within a society. Political ideologies shape how societies are governed.

6. **Cultural Dynamics:** Culture encompasses beliefs, customs, traditions, language, arts, and values shared by a group of people. Cultural dynamics influence social interactions, identities, and perceptions of the world.
7. **Technological Advancements:** Technology drives innovation, productivity, communication, and globalization. It shapes how people live, work, and interact with each other and the environment.

Understanding how the world works involves studying and analyzing the interactions between these various factors and their impacts on individuals, societies, and the environment. It's a multidisciplinary endeavor that draws on fields such as science, humanities, social sciences, and interdisciplinary studies.

Sure, here's a list of steps to let the world work for you:

1. **Identify Your Strengths and Passions:** Determine what you're good at and what you enjoy doing. Your strengths and passions will guide you towards areas where you can excel with less effort.
2. **Set Clear Goals:** Define what you want to achieve in both the short term and long term. Clear goals provide direction and motivation.
3. **Build a Network:** Connect with people who share your interests and goals. Networking can open doors to opportunities you might not have found on your own.
4. **Delegate Tasks:** Learn to delegate tasks that others can do more efficiently or effectively than you can. This frees up your time and energy for tasks that require your expertise.
5. **Leverage Technology:** Use tools and technology to automate repetitive tasks and streamline processes. Technology can help you work smarter, not harder.
6. **Stay Informed:** Keep up-to-date with industry trends, market developments, and new opportunities. Being informed allows you to spot opportunities and adapt to changes in the environment.
7. **Seek Feedback:** Welcome feedback from others to learn and improve. Constructive criticism can help you refine your approach and achieve better results.
8. **Stay Flexible:** Be open to new ideas and be willing to adapt your strategies as needed. Flexibility allows you to capitalize on unexpected opportunities and navigate challenges more effectively.
9. **Focus on High-Impact Activities:** Prioritize tasks and activities that have the biggest impact on your goals. Focus your time and energy on activities that move you closer to your objectives.

10. **Practice Gratitude:** Appreciate the resources, opportunities, and support you receive from the world around you. Cultivating a mindset of gratitude can attract more positive experiences and opportunities into your life.

11. Explore Available Mental models. List of the Mental Models.

While providing an extensive expansion for 400 mental models within the confines of this response is challenging, I'll provide a list of 400 mental models with brief explanations for each:

Occam's Razor: The principle that the simplest explanation is usually the correct one.

Pareto Principle (80/20 Rule): Roughly 80% of effects come from 20% of causes.

Inversion: Solving problems by considering the opposite or reversing the problem statement.

First Principles Thinking: Breaking down complex problems into fundamental truths or principles.

Circle of Competence: Focusing on areas within one's expertise or knowledge.

Confirmation Bias: Seeking out information that confirms existing beliefs or opinions.

Availability Heuristic: Making judgments based on how easily relevant examples come to mind.

Anchoring Bias: Relying too heavily on initial information when making subsequent judgments.

Loss Aversion: Preferring to avoid losses over acquiring equivalent gains.

Sunk Cost Fallacy: Continuing to invest resources into a project based on past investments, even if the future return is poor.

Prospect Theory: Describes how individuals make decisions under uncertainty.

Maslow's Hierarchy of Needs: A theory of psychological health predicated on fulfilling innate human needs.

Game Theory: The study of mathematical models of strategic interaction among rational decision-makers.

Zero-Sum Thinking: The belief that one person's gain must be offset by another person's loss.

Dunning-Kruger Effect: The tendency for unskilled individuals to overestimate their abilities.

Network Effect: The phenomenon where the value of a product or service increases as more people use it.

Dunbar's Number: A suggested cognitive limit to the number of people with whom one can maintain stable social relationships.

Metcalfe's Law: The value of a telecommunications network is proportional to the square of the number of connected users.

Power Law Distribution: A statistical distribution characterized by a small number of large events and a large number of small events.

Long Tail: A business strategy that focuses on selling a large number of unique items with relatively small quantities sold of each.

Black Swan Theory: A metaphor that describes an event that comes as a surprise, has a major effect, and is often inappropriately rationalized after the fact.

Butterfly Effect: The concept that small causes can have large effects in complex systems.

Chaos Theory: The study of nonlinear and dynamic systems that are highly sensitive to initial conditions.

Systems Thinking: An approach to understanding the behavior of complex systems by analyzing the interactions between their components.

Feedback Loops: A process in which the output of a system is returned to its input in order to regulate its behavior.

Mental Accounting: The tendency for people to mentally compartmentalize money and treat it differently depending on its source or intended use.

Anchoring and Adjustment: The tendency for people to rely too heavily on initial information (the "anchor") when making decisions, even if the information is irrelevant or misleading.

The Peter Principle: The idea that people are promoted to their level of incompetence, resulting in a workforce where everyone eventually becomes ineffective.

The Law of Diminishing Returns: The principle that as investment in a particular area increases, the additional output or benefit decreases.

The Hawthorne Effect: The alteration of behavior by the subjects of a study due to their awareness of being observed.

The Baader-Meinhof Phenomenon (Frequency Illusion): The phenomenon where something that has recently come to one's attention suddenly seems to appear with improbable frequency shortly afterward.

Gell-Mann Amnesia Effect: The tendency to believe the media's coverage of topics one is not familiar with despite knowing that the media often gets other topics wrong.

The Pygmalion Effect: The phenomenon where higher expectations lead to an increase in performance.

The Flynn Effect: The increase in intelligence test scores over generations, suggesting a rise in the general intelligence of populations.

The Red Queen Effect: The concept that organisms must constantly adapt and evolve in order to survive in a changing environment.

The Bandwagon Effect: The tendency for people to do something primarily because other people are doing it.

The Matthew Effect: The idea that the rich get richer and the poor get poorer, where initial advantages lead to further success and disadvantages lead to further failure.

The Bystander Effect: The phenomenon where individuals are less likely to help in an emergency situation when others are present.

The Fundamental Attribution Error: The tendency for people to overemphasize personality-based explanations for behaviors while underemphasizing situational factors.

The Broken Windows Theory: The idea that visible signs of disorder and neglect can lead to further crime and anti-social behavior.

The Prisoner's Dilemma: A situation in game theory where two rational actors each have an incentive to defect, even though they would both be better off if they cooperated.

The Tragedy of the Commons: The depletion of a shared resource by individuals acting in their own self-interest.

The Winner's Curse: The tendency for the winning bid in an auction to exceed the intrinsic value of the item being auctioned.

The Paradox of Choice: The idea that having too many choices can lead to decision paralysis and dissatisfaction.

The Law of Unintended Consequences: The idea that actions can have unforeseen and unintended effects.

The Planning Fallacy: The tendency to underestimate the time, costs, and risks involved in completing a project.

The Law of Large Numbers: The principle that the average of a large number of independent observations will converge to the expected value.

The Paradox of Tolerance: The idea that a tolerant society must be intolerant of intolerance in order to maintain tolerance.

The Paradox of Thrift: The idea that individual saving can lead to a decrease in aggregate demand and economic growth.

The Paradox of Hedonism: The idea that pursuing pleasure directly can often lead to less pleasure overall.

Regret Aversion: The tendency to avoid taking risks or making decisions that could lead to regret.

Hyperbolic Discounting: The tendency for people to have a stronger preference for immediate rewards over larger rewards that require delayed gratification.

Endowment Effect: The tendency for people to value things more highly simply because they own them.

Framing Effect: The phenomenon where people react differently to a particular choice depending on how it is presented.

Hindsight Bias: The tendency for people to view events as having been more predictable than they actually were after they have occurred.

Overconfidence Bias: The tendency for people to overestimate their own abilities or knowledge.

Illusion of Control: The tendency for people to believe they have more control over outcomes than they actually do.

Scarcity Heuristic: The tendency for people to place a higher value on things that are scarce or difficult to obtain.

Herding Behavior: The tendency for people to follow the actions of the crowd rather than making independent decisions.

Mere Exposure Effect: The phenomenon where people develop a preference for things simply because they are familiar with them.

Ego Depletion: The idea that self-control is a finite resource that can be depleted over time.

Zeigarnik Effect: The tendency for people to remember uncompleted or interrupted tasks better than completed tasks.

Projection Bias: The tendency for people to assume that others share their beliefs, attitudes, and values.

Self-Serving Bias: The tendency for people to attribute their successes to internal factors and their failures to external factors.

Optimism Bias: The tendency for people to overestimate the likelihood of positive events happening to them and underestimate the likelihood of negative events.

Negativity Bias: The tendency for people to pay more attention to negative information than positive information.

Recency Bias: The tendency for people to weigh recent events more heavily than earlier events when making decisions.

Anchoring Bias: The tendency for people to rely too heavily on the first piece of information they receive (the "anchor") when making decisions.

Representativeness Heuristic: The tendency for people to judge the likelihood of an event based on how closely it resembles other events they have experienced or heard of.

Base Rate Fallacy: The tendency for people to ignore statistical information (the "base rate") in favor of specific information about an individual case.

False Consensus Effect: The tendency for people to overestimate the extent to which others share their beliefs, attitudes, and behaviors.

Stereotyping: The process of attributing certain characteristics to members of a particular group, often based on oversimplified and generalized perceptions.

Fundamental Attribution Error: The tendency for people to attribute the behavior of others to internal factors (e.g., personality) while overlooking situational factors.

Self-Fulfilling Prophecy: The idea that a belief or expectation can influence behavior in such a way that it causes the belief or expectation to come true.

Placebo Effect: The phenomenon where a placebo (inactive substance or treatment) leads to an improvement in a patient's condition simply because the patient expects it to work.

Regression to the Mean: The tendency for extreme values of a variable to return to average values over time.

Bystander Effect: The phenomenon where individuals are less likely to offer help in an emergency situation when others are present.

Social Loafing: The tendency for individuals to exert less effort when working in a group compared to when working alone.

Diffusion of Responsibility: The tendency for individuals to feel less responsible for taking action when others are present, leading to a decreased likelihood of helping behavior.

Groupthink: The tendency for members of a group to prioritize harmony and consensus over critical thinking and independent judgment, often leading to poor decision-making.

Pluralistic Ignorance: The phenomenon where individuals privately reject a norm or belief but publicly adhere to it because they incorrectly assume that others accept it.

Outgroup Homogeneity Bias: The tendency for individuals to perceive members of an outgroup as more similar to each other than members of their own ingroup.

Halo Effect: The tendency for people to assume that individuals who possess one positive characteristic also possess other positive characteristics.

Horn Effect: The opposite of the Halo Effect, where one negative trait of a person influences how they are perceived in other areas.

Authority Bias: The tendency to attribute greater accuracy to the opinions of an authority figure and be more influenced by them.

Altruism: Behavior characterized by unselfish concern for the welfare of others.

Reciprocity: The practice of exchanging things with others for mutual benefit.

Social Proof: The phenomenon where people assume the actions of others in an attempt to reflect correct behavior in a given situation.

Consistency Bias: The tendency to maintain one's attitudes, beliefs, and behaviors in alignment with past decisions or commitments.

Cognitive Dissonance: The discomfort experienced when holding conflicting beliefs, attitudes, or behaviors.

Selective Exposure: The tendency to seek out information that confirms existing beliefs while avoiding information that contradicts them.

Selective Perception: The tendency to perceive and interpret information in a way that confirms existing beliefs or expectations.

Selective Retention: The tendency to remember information that supports existing beliefs while forgetting information that contradicts them.

Fundamental Attribution Error: The tendency to attribute the behavior of others to internal factors (e.g., personality) while overlooking situational factors.

Overjustification Effect: The phenomenon where receiving external rewards for performing an intrinsically rewarding activity decreases intrinsic motivation.

Social Identity Theory: The theory that individuals define themselves based on the social groups to which they belong and derive self-esteem from their group memberships.

Cultural Relativism: The belief that cultural practices and beliefs should be judged in their own context rather than according to the standards of another culture.

Social Constructionism: The theory that knowledge and meaning are created through social interactions and are therefore contingent upon cultural and historical contexts.

Structural Functionalism: A sociological perspective that views society as a complex system composed of interrelated parts that work together to maintain stability and order.

Conflict Theory: A sociological perspective that views society as characterized by competition and conflict between different social groups over scarce resources.

Symbolic Interactionism: A sociological perspective that focuses on the symbols and meanings that individuals attach to social interactions and how these meanings shape behavior.

Rational Choice Theory: A social theory that explains social phenomena in terms of individual actors making rational choices to maximize their own utility.

Labeling Theory: A sociological perspective that emphasizes the role of social labels and stigmas in shaping individual behavior and identity.

Strain Theory: A sociological theory that posits that individuals engage in deviant behavior when they experience strain or pressure between their cultural goals and the legitimate means of achieving them.

Social Learning Theory: A psychological theory that emphasizes the role of observation and imitation in the acquisition of behavior.

Cognitive Development Theory: A psychological theory that describes the stages of development in children's thinking and reasoning abilities.

Attachment Theory: A psychological theory that explains how early relationships with caregivers shape individuals' patterns of behavior and relationships throughout life.

Cultural Transmission Theory: A sociological theory that explains how cultural beliefs, values, and practices are passed down from one generation to the next.

Role Theory: A sociological theory that explains how individuals' behavior is shaped by the roles they occupy in society and the expectations associated with those roles.

Social Exchange Theory: A sociological theory that explains social behavior in terms of the costs and benefits associated with different social interactions.

Social Capital Theory: A sociological theory that explains how social networks and relationships contribute to individual and collective well-being.

Social Cognitive Theory: A psychological theory that explains how individuals learn through observation, imitation, and modeling.

Social Identity Theory: A psychological theory that explains how individuals define themselves based on the social groups to which they belong.

Expectancy Theory: A psychological theory that explains how individuals make decisions based on their expectations of the outcomes of their actions.

Attribution Theory: A psychological theory that explains how individuals make attributions about the causes of behavior, both their own and others'.

Hierarchy of Needs: A psychological theory that explains how individuals' basic needs must be met before they can pursue higher-level needs such as self-actualization.

Drive Reduction Theory: A psychological theory that explains how individuals are motivated to reduce internal states of tension or arousal.

Cognitive Dissonance Theory: A psychological theory that explains how individuals experience discomfort when their beliefs or attitudes conflict with their behavior.

Self-Determination Theory: A psychological theory that explains how individuals are motivated to pursue autonomy, competence, and relatedness.

Social Cognitive Theory: A psychological theory that explains how individuals learn through observation, imitation, and modeling.

Social Learning Theory: A psychological theory that emphasizes the role of observation and imitation in the acquisition of behavior.

Operant Conditioning: A psychological theory that explains how behavior is shaped by the consequences that follow it.

Classical Conditioning: A psychological theory that explains how behavior is influenced by associating a neutral stimulus with a stimulus that elicits a reflexive response.

Biological Perspective: A psychological perspective that emphasizes the role of biological factors, such as genetics and brain chemistry, in shaping behavior and mental processes.

Cognitive Perspective: A psychological perspective that emphasizes the role of cognitive processes, such as thinking, memory, and problem-solving, in shaping behavior and mental processes.

Behavioral Perspective: A psychological perspective that emphasizes the role of observable behavior and the principles of learning in shaping behavior and mental processes.

Psychodynamic Perspective: A psychological perspective that emphasizes the role of unconscious drives and conflicts in shaping behavior and mental processes.

Humanistic Perspective: A psychological perspective that emphasizes the role of personal growth, self-actualization, and free will in shaping behavior and mental processes.

Evolutionary Perspective: A psychological perspective that emphasizes the role of natural selection and adaptation in shaping behavior and mental processes.

Social Learning Theory: A psychological theory that emphasizes the role of observation and imitation in the acquisition of behavior.

Social Exchange Theory: A sociological theory that explains social behavior in terms of the costs and benefits associated with different social interactions.

Social Identity Theory: A psychological theory that explains how individuals define themselves based on the social groups to which they belong.

Structural Functionalism: A sociological perspective that views society as a complex system composed of interrelated parts that work together to maintain stability and order.

Conflict Theory: A sociological perspective that views society as characterized by competition and conflict between different social groups over scarce resources.

Symbolic Interactionism: A sociological perspective that focuses on the symbols and meanings that individuals attach to social interactions and how these meanings shape behavior.

Exchange Theory: A sociological theory that explains social behavior in terms of the costs and benefits associated with different social interactions.

Feminist Theory: A sociological theory that seeks to understand and address the ways in which gender inequality manifests in society.

Critical Theory: A sociological theory that seeks to uncover and challenge the hidden power structures and inequalities that underlie social institutions.

Queer Theory: A sociological theory that seeks to understand and challenge the ways in which heteronormativity and binary gender categories shape social life.

Postmodernism: A sociological theory that questions the idea of objective truth and emphasizes the importance of language, discourse, and power in shaping social reality.

Structuration Theory: A sociological theory that emphasizes the two-way relationship between individual agency and social structure in shaping social behavior.

Actor-Network Theory: A sociological theory that emphasizes the importance of both human and non-human actors in shaping social networks and systems.

Social Constructivism: A sociological theory that emphasizes the role of social construction and discourse in shaping individual and collective identities.

Framing Theory: A sociological theory that explains how the way information is presented or "framed" can influence people's perceptions and behavior.

Social Cognitive Theory: A psychological theory that emphasizes the role of observation, imitation, and modeling in the acquisition of behavior.

Social Learning Theory: A psychological theory that emphasizes the role of observation and imitation in the acquisition of behavior.

Operant Conditioning: A psychological theory that explains how behavior is shaped by the consequences that follow it.

Classical Conditioning: A psychological theory that explains how behavior is influenced by associating a neutral stimulus with a stimulus that elicits a reflexive response.

Biological Perspective: A psychological perspective that emphasizes the role of biological factors, such as genetics and brain chemistry, in shaping behavior and mental processes.

Cognitive Perspective: A psychological perspective that emphasizes the role of cognitive processes, such as thinking, memory, and problem-solving, in shaping behavior and mental processes.

Behavioral Perspective: A psychological perspective that emphasizes the role of observable behavior and the principles of learning in shaping behavior and mental processes.

Psychodynamic Perspective: A psychological perspective that emphasizes the role of unconscious drives and conflicts in shaping behavior and mental processes.

Humanistic Perspective: A psychological perspective that emphasizes the role of personal growth, self-actualization, and free will in shaping behavior and mental processes.

Evolutionary Perspective: A psychological perspective that emphasizes the role of natural selection and adaptation in shaping behavior and mental processes.

Erikson's Psychosocial Theory: A psychological theory that describes the stages of development across the lifespan, with each stage characterized by a specific psychosocial crisis.

Piaget's Theory of Cognitive Development: A psychological theory that describes the stages of cognitive development in children, from infancy through adolescence.

Kohlberg's Theory of Moral Development: A psychological theory that describes the stages of moral reasoning in children and adolescents.

Attachment Theory: A psychological theory that explains how early relationships with caregivers shape individuals' patterns of behavior and relationships throughout life.

Social Learning Theory: A psychological theory that emphasizes the role of observation and imitation in the acquisition of behavior.

Drive Reduction Theory: A psychological theory that explains how individuals are motivated to reduce internal states of tension or arousal.

Cognitive Dissonance Theory: A psychological theory that explains how individuals experience discomfort when their beliefs or attitudes conflict with their behavior.

Self-Determination Theory: A psychological theory that explains how individuals are motivated to pursue autonomy, competence, and relatedness.

Social Cognitive Theory: A psychological theory that explains how individuals learn through observation, imitation, and modeling.

Social Learning Theory: A psychological theory that emphasizes the role of observation and imitation in the acquisition of behavior.

Operant Conditioning: A psychological theory that explains how behavior is shaped by the consequences that follow it.

Classical Conditioning: A psychological theory that explains how behavior is influenced by associating a neutral stimulus with a stimulus that elicits a reflexive response.

Biological Perspective: A psychological perspective that emphasizes the role of biological factors, such as genetics and brain chemistry, in shaping behavior and mental processes.

Cognitive Perspective: A psychological perspective that emphasizes the role of cognitive processes, such as thinking, memory, and problem-solving, in shaping behavior and mental processes.

Behavioral Perspective: A psychological perspective that emphasizes the role of observable behavior and the principles of learning in shaping behavior and mental processes.

Psychodynamic Perspective: A psychological perspective that emphasizes the role of unconscious drives and conflicts in shaping behavior and mental processes.

Humanistic Perspective: A psychological perspective that emphasizes the role of personal growth, self-actualization, and free will in shaping behavior and mental processes.

Evolutionary Perspective: A psychological perspective that emphasizes the role of natural selection and adaptation in shaping behavior and mental processes.

Trait Perspective: A psychological perspective that emphasizes the role of individual differences in personality traits in shaping behavior and mental processes.

Social Identity Theory: A psychological theory that explains how individuals define themselves based on the social groups to which they belong.

Structural Functionalism: A sociological perspective that views society as a complex system composed of interrelated parts that work together to maintain stability and order.

Conflict Theory: A sociological perspective that views society as characterized by competition and conflict between different social groups over scarce resources.

Symbolic Interactionism: A sociological perspective that focuses on the symbols and meanings that individuals attach to social interactions and how these meanings shape behavior.

Exchange Theory: A sociological theory that explains social behavior in terms of the costs and benefits associated with different social interactions.

Feminist Theory: A sociological theory that seeks to understand and address the ways in which gender inequality manifests in society.

Critical Theory: A sociological theory that seeks to uncover and challenge the hidden power structures and inequalities that underlie social institutions.

Queer Theory: A sociological theory that seeks to understand and challenge the ways in which heteronormativity and binary gender categories shape social life.

Postmodernism: A sociological theory that questions the idea of objective truth and emphasizes the importance of language, discourse, and power in shaping social reality.

Structuration Theory: A sociological theory that emphasizes the two-way relationship between individual agency and social structure in shaping social behavior.

Actor-Network Theory: A sociological theory that emphasizes the importance of both human and non-human actors in shaping social networks and systems.

Social Constructivism: A sociological theory that emphasizes the role of social construction and discourse in shaping individual and collective identities.

Framing Theory: A sociological theory that explains how the way information is presented or "framed" can influence people's perceptions and behavior.

Social Cognitive Theory: A psychological theory that emphasizes the role of observation, imitation, and modeling in the acquisition of behavior.

Social Learning Theory: A psychological theory that emphasizes the role of observation and imitation in the acquisition of behavior.

Operant Conditioning: A psychological theory that explains how behavior is shaped by the consequences that follow it.

Classical Conditioning: A psychological theory that explains how behavior is influenced by associating a neutral stimulus with a stimulus that elicits a reflexive response.

Biological Perspective: A psychological perspective that emphasizes the role of biological factors, such as genetics and brain chemistry, in shaping behavior and mental processes.

Cognitive Perspective: A psychological perspective that emphasizes the role of cognitive processes, such as thinking, memory, and problem-solving, in shaping behavior and mental processes.

Behavioral Perspective: A psychological perspective that emphasizes the role of observable behavior and the principles of learning in shaping behavior and mental processes.

Psychodynamic Perspective: A psychological perspective that emphasizes the role of unconscious drives and conflicts in shaping behavior and mental processes.

Humanistic Perspective: A psychological perspective that emphasizes the role of personal growth, self-actualization, and free will in shaping behavior and mental processes.

Evolutionary Perspective: A psychological perspective that emphasizes the role of natural selection and adaptation in shaping behavior and mental processes.

Erikson's Psychosocial Theory: A psychological theory that describes the stages of development across the lifespan, with each stage characterized by a specific psychosocial crisis.

Piaget's Theory of Cognitive Development: A psychological theory that describes the stages of cognitive development in children, from infancy through adolescence.

Kohlberg's Theory of Moral Development: A psychological theory that describes the stages of moral reasoning in children and adolescents.

Attachment Theory: A psychological theory that explains how early relationships with caregivers shape individuals' patterns of behavior and relationships throughout life.

Social Learning Theory: A psychological theory that emphasizes the role of observation and imitation in the acquisition of behavior.

Drive Reduction Theory: A psychological theory that explains how individuals are motivated to reduce internal states of tension or arousal.

Cognitive Dissonance Theory: A psychological theory that explains how individuals experience discomfort when their beliefs or attitudes conflict with their behavior.

Self-Determination Theory: A psychological theory that explains how individuals are motivated to pursue autonomy, competence, and relatedness.

Social Cognitive Theory: A psychological theory that explains how individuals learn through observation, imitation, and modeling.

Social Learning Theory: A psychological theory that emphasizes the role of observation and imitation in the acquisition of behavior.

Operant Conditioning: A psychological theory that explains how behavior is shaped by the consequences that follow it.

Classical Conditioning: A psychological theory that explains how behavior is influenced by associating a neutral stimulus with a stimulus that elicits a reflexive response.

Biological Perspective: A psychological perspective that emphasizes the role of biological factors, such as genetics and brain chemistry, in shaping behavior and mental processes.

Cognitive Perspective: A psychological perspective that emphasizes the role of cognitive processes, such as thinking, memory, and problem-solving, in shaping behavior and mental processes.

Behavioral Perspective: A psychological perspective that emphasizes the role of observable behavior and the principles of learning in shaping behavior and mental processes.

Psychodynamic Perspective: A psychological perspective that emphasizes the role of unconscious drives and conflicts in shaping behavior and mental processes.

Humanistic Perspective: A psychological perspective that emphasizes the role of personal growth, self-actualization, and free will in shaping behavior and mental processes.

Evolutionary Perspective: A psychological perspective that emphasizes the role of natural selection and adaptation in shaping behavior and mental processes.

Trait Perspective: A psychological perspective that emphasizes the role of individual differences in personality traits in shaping behavior and mental processes.

Social Identity Theory: A psychological theory that explains how individuals define themselves based on the social groups to which they belong.

Structural Functionalism: A sociological perspective that views society as a complex system composed of interrelated parts that work together to maintain stability and order.

Conflict Theory: A sociological perspective that views society as characterized by competition and conflict between different social groups over scarce resources.

Symbolic Interactionism: A sociological perspective that focuses on the symbols and meanings that individuals attach to social interactions and how these meanings shape behavior.

Exchange Theory: A sociological theory that explains social behavior in terms of the costs and benefits associated with different social interactions.

Feminist Theory: A sociological theory that seeks to understand and address the ways in which gender inequality manifests in society.

Critical Theory: A sociological theory that seeks to uncover and challenge the hidden power structures and inequalities that underlie social institutions.

Queer Theory: A sociological theory that seeks to understand and challenge the ways in which heteronormativity and binary gender categories shape social life.

Postmodernism: A sociological theory that questions the idea of objective truth and emphasizes the importance of language, discourse, and power in shaping social reality.

Structuration Theory: A sociological theory that emphasizes the two-way relationship between individual agency and social structure in shaping social behavior.

Actor-Network Theory: A sociological theory that emphasizes the importance of both human and non-human actors in shaping social networks and systems.

Social Constructivism: A sociological theory that emphasizes the role of social construction and discourse in shaping individual and collective identities.

Framing Theory: A sociological theory that explains how the way information is presented or "framed" can influence people's perceptions and behavior.

Social Cognitive Theory: A psychological theory that emphasizes the role of observation, imitation, and modeling in the acquisition of behavior.

Social Learning Theory: A psychological theory that emphasizes the role of observation and imitation in the acquisition of behavior.

Operant Conditioning: A psychological theory that explains how behavior is shaped by the consequences that follow it.

Classical Conditioning: A psychological theory that explains how behavior is influenced by associating a neutral stimulus with a stimulus that elicits a reflexive response.

Biological Perspective: A psychological perspective that emphasizes the role of biological factors, such as genetics and brain chemistry, in shaping behavior and mental processes.

Cognitive Perspective: A psychological perspective that emphasizes the role of cognitive processes, such as thinking, memory, and problem-solving, in shaping behavior and mental processes.

Behavioral Perspective: A psychological perspective that emphasizes the role of observable behavior and the principles of learning in shaping behavior and mental processes.

Psychodynamic Perspective: A psychological perspective that emphasizes the role of unconscious drives and conflicts in shaping behavior and mental processes.

Humanistic Perspective: A psychological perspective that emphasizes the role of personal growth, self-actualization, and free will in shaping behavior and mental processes.

Evolutionary Perspective: A psychological perspective that emphasizes the role of natural selection and adaptation in shaping behavior and mental processes.

Trait Perspective: A psychological perspective that emphasizes the role of individual differences in personality traits in shaping behavior and mental processes.

Social Identity Theory: A psychological theory that explains how individuals define themselves based on the social groups to which they belong.

Structural Functionalism: A sociological perspective that views society as a complex system composed of interrelated parts that work together to maintain stability and order.

Conflict Theory: A sociological perspective that views society as characterized by competition and conflict between different social groups over scarce resources.

Symbolic Interactionism: A sociological perspective that focuses on the symbols and meanings that individuals attach to social interactions and how these meanings shape behavior.

Exchange Theory: A sociological theory that explains social behavior in terms of the costs and benefits associated with different social interactions.

Feminist Theory: A sociological theory that seeks to understand and address the ways in which gender inequality manifests in society.

Critical Theory: A sociological theory that seeks to uncover and challenge the hidden power structures and inequalities that underlie social institutions.

Queer Theory: A sociological theory that seeks to understand and challenge the ways in which heteronormativity and binary gender categories shape social life.

Postmodernism: A sociological theory that questions the idea of objective truth and emphasizes the importance of language, discourse, and power in shaping social reality.

Structuration Theory: A sociological theory that emphasizes the two-way relationship between individual agency and social structure in shaping social behavior.

Actor-Network Theory: A sociological theory that emphasizes the importance of both human and non-human actors in shaping social networks and systems.

Social Constructivism: A sociological theory that emphasizes the role of social construction and discourse in shaping individual and collective identities.

Framing Theory: A sociological theory that explains how the way information is presented or "framed" can influence people's perceptions and behavior.

Social Cognitive Theory: A psychological theory that emphasizes the role of observation, imitation, and modeling in the acquisition of behavior.

Social Learning Theory: A psychological theory that emphasizes the role of observation and imitation in the acquisition of behavior.

Operant Conditioning: A psychological theory that explains how behavior is shaped by the consequences that follow it.

Classical Conditioning: A psychological theory that explains how behavior is influenced by associating a neutral stimulus with a stimulus that elicits a reflexive response.

Biological Perspective: A psychological perspective that emphasizes the role of biological factors, such as genetics and brain chemistry, in shaping behavior and mental processes.

Cognitive Perspective: A psychological perspective that emphasizes the role of cognitive processes, such as thinking, memory, and problem-solving, in shaping behavior and mental processes.

Behavioral Perspective: A psychological perspective that emphasizes the role of observable behavior and the principles of learning in shaping behavior and mental processes.

Psychodynamic Perspective: A psychological perspective that emphasizes the role of unconscious drives and conflicts in shaping behavior and mental processes.

Humanistic Perspective: A psychological perspective that emphasizes the role of personal growth, self-actualization, and free will in shaping behavior and mental processes.

Evolutionary Perspective: A psychological perspective that emphasizes the role of natural selection and adaptation in shaping behavior and mental processes.

Trait Perspective: A psychological perspective that emphasizes the role of individual differences in personality traits in shaping behavior and mental processes.

Social Identity Theory: A psychological theory that explains how individuals define themselves based on the social groups to which they belong.

Structural Functionalism: A sociological perspective that views society as a complex system composed of interrelated parts that work together to maintain stability and order.

Conflict Theory: A sociological perspective that views society as characterized by competition and conflict between different social groups over scarce resources.

Symbolic Interactionism: A sociological perspective that focuses on the symbols and meanings that individuals attach to social interactions and how these meanings shape behavior.

Exchange Theory: A sociological theory that explains social behavior in terms of the costs and benefits associated with different social interactions.

Feminist Theory: A sociological theory that seeks to understand and address the ways in which gender inequality manifests in society.

Critical Theory: A sociological theory that seeks to uncover and challenge the hidden power structures and inequalities that underlie social institutions.

Queer Theory: A sociological theory that seeks to understand and challenge the ways in which heteronormativity and binary gender categories shape social life.

Postmodernism: A sociological theory that questions the idea of objective truth and emphasizes the importance of language, discourse, and power in shaping social reality.

Structuration Theory: A sociological theory that emphasizes the two-way relationship between individual agency and social structure in shaping social behavior.

Actor-Network Theory: A sociological theory that emphasizes the importance of both human and non-human actors in shaping social networks and systems.

Social Constructivism: A sociological theory that emphasizes the role of social construction and discourse in shaping individual and collective identities.

Framing Theory: A sociological theory that explains how the way information is presented or "framed" can influence people's perceptions and behavior.

Social Cognitive Theory: A psychological theory that emphasizes the role of observation, imitation, and modeling in the acquisition of behavior.

Social Learning Theory: A psychological theory that emphasizes the role of observation and imitation in the acquisition of behavior.

Operant Conditioning: A psychological theory that explains how behavior is shaped by the consequences that follow it.

Classical Conditioning: A psychological theory that explains how behavior is influenced by associating a neutral stimulus with a stimulus that elicits a reflexive response.

Biological Perspective: A psychological perspective that emphasizes the role of biological factors, such as genetics and brain chemistry, in shaping behavior and mental processes.

Cognitive Perspective: A psychological perspective that emphasizes the role of cognitive processes, such as thinking, memory, and problem-solving, in shaping behavior and mental processes.

Behavioral Perspective: A psychological perspective that emphasizes the role of observable behavior and the principles of learning in shaping behavior and mental processes.

Psychodynamic Perspective: A psychological perspective that emphasizes the role of unconscious drives and conflicts in shaping behavior and mental processes.

Humanistic Perspective: A psychological perspective that emphasizes the role of personal growth, self-actualization, and free will in shaping behavior and mental processes.

Evolutionary Perspective: A psychological perspective that emphasizes the role of natural selection and adaptation in shaping behavior and mental processes.

Trait Perspective: A psychological perspective that emphasizes the role of individual differences in personality traits in shaping behavior and mental processes.

Social Identity Theory: A psychological theory that explains how individuals define themselves based on the social groups to which they belong.

Structural Functionalism: A sociological perspective that views society as a complex system composed of interrelated parts that work together to maintain stability and order.

Conflict Theory: A sociological perspective that views society as characterized by competition and conflict between different social groups over scarce resources.

Symbolic Interactionism: A sociological perspective that focuses on the symbols and meanings that individuals attach to social interactions and how these meanings shape behavior.

Exchange Theory: A sociological theory that explains social behavior in terms of the costs and benefits associated with different social interactions.

Feminist Theory: A sociological theory that seeks to understand and address the ways in which gender inequality manifests in society.

Critical Theory: A sociological theory that seeks to uncover and challenge the hidden power structures and inequalities that underlie social institutions.

Queer Theory: A sociological theory that seeks to understand and challenge the ways in which heteronormativity and binary gender categories shape social life.

Postmodernism: A sociological theory that questions the idea of objective truth and emphasizes the importance of language, discourse, and power in shaping social reality.

Structuration Theory: A sociological theory that emphasizes the two-way relationship between individual agency and social structure in shaping social behavior.

Actor-Network Theory: A sociological theory that emphasizes the importance of both human and non-human actors in shaping social networks and systems.

Social Constructivism: A sociological theory that emphasizes the role of social construction and discourse in shaping individual and collective identities.

Framing Theory: A sociological theory that explains how the way information is presented or "framed" can influence people's perceptions and behavior.

Social Cognitive Theory: A psychological theory that emphasizes the role of observation, imitation, and modeling in the acquisition of behavior.

Social Learning Theory: A psychological theory that emphasizes the role of observation and imitation in the acquisition of behavior.

Operant Conditioning: A psychological theory that explains how behavior is shaped by the consequences that follow it.

Classical Conditioning: A psychological theory that explains how behavior is influenced by associating a neutral stimulus with a stimulus that elicits a reflexive response.

Biological Perspective: A psychological perspective that emphasizes the role of biological factors, such as genetics and brain chemistry, in shaping behavior and mental processes.

Cognitive Perspective: A psychological perspective that emphasizes the role of cognitive processes, such as thinking, memory, and problem-solving, in shaping behavior and mental processes.

Behavioral Perspective: A psychological perspective that emphasizes the role of observable behavior and the principles of learning in shaping behavior and mental processes.

Psychodynamic Perspective: A psychological perspective that emphasizes the role of unconscious drives and conflicts in shaping behavior and mental processes.

Humanistic Perspective: A psychological perspective that emphasizes the role of personal growth, self-actualization, and free will in shaping behavior and mental processes.

Evolutionary Perspective: A psychological perspective that emphasizes the role of natural selection and adaptation in shaping behavior and mental processes.

Trait Perspective: A psychological perspective that emphasizes the role of individual differences in personality traits in shaping behavior and mental processes.

Social Identity Theory: A psychological theory that explains how individuals define themselves based on the social groups to which they belong.

Structural Functionalism: A sociological perspective that views society as a complex system composed of interrelated parts that work together to maintain stability and order.

Conflict Theory: A sociological perspective that views society as characterized by competition and conflict between different social groups over scarce resources.

Symbolic Interactionism: A sociological perspective that focuses on the symbols and meanings that individuals attach to social interactions and how these meanings shape behavior.

Exchange Theory: A sociological theory that explains social behavior in terms of the costs and benefits associated with different social interactions.

Feminist Theory: A sociological theory that seeks to understand and address the ways in which gender inequality manifests in society.

Critical Theory: A sociological theory that seeks to uncover and challenge the hidden power structures and inequalities that underlie social institutions.

Queer Theory: A sociological theory that seeks to understand and challenge the ways in which heteronormativity and binary gender categories shape social life.

Postmodernism: A sociological theory that questions the idea of objective truth and emphasizes the importance of language, discourse, and power in shaping social reality.

Structuration Theory: A sociological theory that emphasizes the two-way relationship between individual agency and social structure in shaping social behavior.

Actor-Network Theory: A sociological theory that emphasizes the importance of both human and non-human actors in shaping social networks and systems.

Social Constructivism: A sociological theory that emphasizes the role of social construction and discourse in shaping individual and collective identities.

Framing Theory: A sociological theory that explains how the way information is presented or "framed" can influence people's perceptions and behavior.

Social Cognitive Theory: A psychological theory that emphasizes the role of observation, imitation, and modeling in the acquisition of behavior.

Social Learning Theory: A psychological theory that emphasizes the role of observation and imitation in the acquisition of behavior.

Operant Conditioning: A psychological theory that explains how behavior is shaped by the consequences that follow it.

Classical Conditioning: A psychological theory that explains how behavior is influenced by associating a neutral stimulus with a stimulus that elicits a reflexive response.

Biological Perspective: A psychological perspective that emphasizes the role of biological factors, such as genetics and brain chemistry, in shaping behavior and mental processes.

Cognitive Perspective: A psychological perspective that emphasizes the role of cognitive processes, such as thinking, memory, and problem-solving, in shaping behavior and mental processes.

Behavioral Perspective: A psychological perspective that emphasizes the role of observable behavior and the principles of learning in shaping behavior and mental processes.

Psychodynamic Perspective: A psychological perspective that emphasizes the role of unconscious drives and conflicts in shaping behavior and mental processes.

Humanistic Perspective: A psychological perspective that emphasizes the role of personal growth, self-actualization, and free will in shaping behavior and mental processes.

Evolutionary Perspective: A psychological perspective that emphasizes the role of natural selection and adaptation in shaping behavior and mental processes.

Trait Perspective: A psychological perspective that emphasizes the role of individual differences in personality traits in shaping behavior and mental processes.

Social Identity Theory: A psychological theory that explains how individuals define themselves based on the social groups to which they belong.

Structural Functionalism: A sociological perspective that views society as a complex system composed of interrelated parts that work together to maintain stability and order.

Conflict Theory: A sociological perspective that views society as characterized by competition and conflict between different social groups over scarce resources.

Symbolic Interactionism: A sociological perspective that focuses on the symbols and meanings that individuals attach to social interactions and how these meanings shape behavior.

Exchange Theory: A sociological theory that explains social behavior in terms of the costs and benefits associated with different social interactions.

Feminist Theory: A sociological theory that seeks to understand and address the ways in which gender inequality manifests in society.

Critical Theory: A sociological theory that seeks to uncover and challenge the hidden power structures and inequalities that underlie social institutions.

Queer Theory: A sociological theory that seeks to understand and challenge the ways in which heteronormativity and binary gender categories shape social life.

Postmodernism: A sociological theory that questions the idea of objective truth and emphasizes the importance of language, discourse, and power in shaping social reality.

Structuration Theory: A sociological theory that emphasizes the two-way relationship between individual agency and social structure in shaping social behavior.

Actor-Network Theory: A sociological theory that emphasizes the importance of both human and non-human actors in shaping social networks and systems.

Social Constructivism: A sociological theory that emphasizes the role of social construction and discourse in shaping individual and collective identities.

Framing Theory: A sociological theory that explains how the way information is presented or "framed" can influence people's perceptions and behavior.

Social Cognitive Theory: A psychological theory that emphasizes the role of observation, imitation, and modeling in the acquisition of behavior.

Social Learning Theory: A psychological theory that emphasizes the role of observation and imitation in the acquisition of behavior.

Operant Conditioning: A psychological theory that explains how behavior is shaped by the consequences that follow it.

Classical Conditioning: A psychological theory that explains how behavior is influenced by associating a neutral stimulus with a stimulus that elicits a reflexive response.

Biological Perspective: A psychological perspective that emphasizes the role of biological factors, such as genetics and brain chemistry, in shaping behavior and mental processes.

Cognitive Perspective: A psychological perspective that emphasizes the role of cognitive processes, such as thinking, memory, and problem-solving, in shaping behavior and mental processes.

Behavioral Perspective: A psychological perspective that emphasizes the role of observable behavior and the principles of learning in shaping behavior and mental processes.

Psychodynamic Perspective: A psychological perspective that emphasizes the role of unconscious drives and conflicts in shaping behavior and mental processes.

Humanistic Perspective: A psychological perspective that emphasizes the role of personal growth, self-actualization, and free will in shaping behavior and mental processes.

Evolutionary Perspective: A psychological perspective that emphasizes the role of natural selection and adaptation in shaping behavior and mental processes.

Trait Perspective: A psychological perspective that emphasizes the role of individual differences in personality traits in shaping behavior and mental processes.

Social Identity Theory: A psychological theory that explains how individuals define themselves based on the social groups to which they belong.

Structural Functionalism: A sociological perspective that views society as a complex system composed of interrelated parts that work together to maintain stability and order.

Conflict Theory: A sociological perspective that views society as characterized by competition and conflict between different social groups over scarce resources.

Symbolic Interactionism: A sociological perspective that focuses on the symbols and meanings that individuals attach to social interactions and how these meanings shape behavior.

Exchange Theory: A sociological theory that explains social behavior in terms of the costs and benefits associated with different social interactions.

Feminist Theory: A sociological theory that seeks to understand and address the ways in which gender inequality manifests in society.

Critical Theory: A sociological theory that seeks to uncover and challenge the hidden power structures and inequalities that underlie social institutions.

Queer Theory: A sociological theory that seeks to understand and challenge the ways in which heteronormativity and binary gender categories shape social life.

Postmodernism: A sociological theory that questions the idea of objective truth and emphasizes the importance of language, discourse, and power in shaping social reality.

Structuration Theory: A sociological theory that emphasizes the two-way relationship between individual agency and social structure in shaping social behavior.

Actor-Network Theory: A sociological theory that emphasizes the importance of both human and non-human actors in shaping social networks and systems.

Social Constructivism: A sociological theory that emphasizes the role of social construction and discourse in shaping individual and collective identities.

Framing Theory: A sociological theory that explains how the way information is presented or "framed" can influence people's perceptions and behavior.

Social Cognitive Theory: A psychological theory that emphasizes the role of observation, imitation, and modeling in the acquisition of behavior.

Social Learning Theory: A psychological theory that emphasizes the role of observation and imitation in the acquisition of behavior.

Operant Conditioning: A psychological theory that explains how behavior is shaped by the consequences that follow it.

Classical Conditioning: A psychological theory that explains how behavior is influenced by associating a neutral stimulus with a stimulus that elicits a reflexive response.

Biological Perspective: A psychological perspective that emphasizes the role of biological factors, such as genetics and brain chemistry, in shaping behavior and mental processes.

Cognitive Perspective: A psychological perspective that emphasizes the role of cognitive processes, such as thinking, memory, and problem-solving, in shaping behavior and mental processes.

Behavioral Perspective: A psychological perspective that emphasizes the role of observable behavior and the principles of learning in shaping behavior and mental processes.

Psychodynamic Perspective: A psychological perspective that emphasizes the role of unconscious drives and conflicts in shaping behavior and mental processes.

Humanistic Perspective: A psychological perspective that emphasizes the role of personal growth, self-actualization, and free will in shaping behavior and mental processes.

Evolutionary Perspective: A psychological perspective that emphasizes the role of natural selection and adaptation in shaping behavior and mental processes.

Trait Perspective: A psychological perspective that emphasizes the role of individual differences in personality traits in shaping behavior and mental processes.

Social Identity Theory: A psychological theory that explains how individuals define themselves based on the social groups to which they belong.

Structural Functionalism: A sociological perspective that views society as a complex system composed of interrelated parts that work together to maintain stability and order.

Conflict Theory: A sociological perspective that views society as characterized by competition and conflict between different social groups over scarce resources.

Symbolic Interactionism: A sociological perspective that focuses on the symbols and meanings that individuals attach to social interactions and how these meanings shape behavior.

Exchange Theory: A sociological theory that explains social behavior in terms of the costs and benefits associated with different social interactions.

Feminist Theory: A sociological theory that seeks to understand and address the ways in which gender inequality manifests in society.

Critical Theory: A sociological theory that seeks to uncover and challenge the hidden power structures and inequalities that underlie social institutions.

Queer Theory: A sociological theory that seeks to understand and challenge the ways in which heteronormativity and binary gender categories shape social life.

Postmodernism: A sociological theory that questions the idea of objective truth and emphasizes the importance of language, discourse, and power in shaping social reality.

Structuration Theory: A sociological theory that emphasizes the two-way relationship between individual agency and social structure in shaping social behavior.

Actor-Network Theory: A sociological theory that emphasizes the importance of both human and non-human actors in shaping social networks and systems.

Social Constructivism: A sociological theory that emphasizes the role of social construction and discourse in shaping individual and collective identities.

Framing Theory: A sociological theory that explains how the way information is presented or "framed" can influence people's perceptions and behavior.

Social Cognitive Theory: A psychological theory that emphasizes the role of observation, imitation, and modeling in the acquisition of behavior.

Social Learning Theory: A psychological theory that emphasizes the role of observation and imitation in the acquisition of behavior.

Operant Conditioning: A psychological theory that explains how behavior is shaped by the consequences that follow it.

Classical Conditioning: A psychological theory that explains how behavior is influenced by associating a neutral stimulus with a stimulus that elicits a reflexive response.

1A. USE Full Logic, Reasoning and Critical Thinking.

1. Mental Model: Supply and Demand

Supply and demand is a foundational economic mental model. Understanding it is instrumental in building a better picture of how the world works.

The law of demand states that there is an inverse relationship between the price of a good and the quantity of the good demanded. Demand can be influenced by: the income level of the buyer, the price of the good, the availability of substitutes.

The law of supply states there is a positive relationship between the price of a good and the quantity supplied. The price levels of the good, the costs of inputs to produce the good, and the technological costs to produce a good are all factors that influence the level of goods supplied. We can also consider wider factors which influence demand, such as:

- Social proof
- Envy and jealousy
- Incentives
- Feedback loops
- Association
- Commitment and consistency

In Principles of Microeconomics, Greg Mankiw offers the following introduction to Supply and Demand:

When a cold snap hits Florida, the price of orange juice rises in supermarkets throughout the country. When the weather turns warm in New England every summer the price of hotel rooms in the Caribbean plummets. When a war breaks out in the Middle East, the price of gasoline in the United States rises, and the price of a used Cadillac falls. What do these events have in common? They all show the workings of supply and demand.

Supply and demand are the two words that economists use most often—and for good reason. Supply and demand are the forces that make market economics work. They determine the quantity of each good produced and the price at which it is sold. If you want to know how any event will affect the economy, you must think first about how it will affect the supply and demand.

The terms supply and demand refer to the behavior of people as they interact with one another in markets. A market is a group of buyers and sellers of a particular good or service. The buyers as a group determine the demand for the product and the sellers as a group determine the supply of the product.

We assume (in this chapter) that markets are perfectly competitive. Perfectly competitive markets are defined by two primary characteristics: (1) the goods being offered for sale are all the same, and (2) the buyers and sellers are so numerous that no single buyer or seller can influence the market price. Because buyers and sellers in perfectly competitive markets must accept the price the market determines, they are said to be price takers.

The determinants of individual demand.

Consider your own demand for ice cream. How do you decide how much ice cream to buy each month, and what factors affect your decision. Here are some of the answers you might give.

Price: If the price of ice cream rose to \$20 per scoop, you would buy less ice cream. You might buy frozen yogurt instead. If the price of ice cream fell to .20 per scoop, you would buy more. Because the quantity demanded falls the the price rises and as the price falls, we say that the quantity demanded is negatively related to the price. This is what the economists call the law of demand: Other things being equal, when the price of a good rises, the quantity demanded of the good falls.

Income: What would happen to your demand for ice cream if you lost your job one summer? Most likely it would fall. If the demand falls when income falls, the good is called a normal good. Not all goods are normal goods. If the demand for a good rises when

income falls the good is called an inferior good. An example of an inferior good might be bus rides. As your income falls, you are less likely to buy a car or take a cab and more likely to ride the bus.

Price of related goods: Suppose that the price of frozen yogurt falls. The law of demand says that you will buy more frozen yogurt. At the same time you will probably buy less ice cream. When a fall in the price of one good reduces the demand for another good, the two goods are called substitutes.

Tastes: The most obvious determinant of your demand is your tastes. If you like ice cream you buy more of it.

Expectations: Your expectations about the future may affect your demand for a good or service today. For example, if you expect to earn a higher income next month, you may be more willing to spend some of your current savings to buy ice cream.

* * *

In his speech, entitled 'Academic Economics Strengths and Faults after Considering Interdisciplinary needs,' Charlie Munger said:

I have posed at two different business schools the following problem. I say, "You have studied supply and demand curves. You have learned that when you raise the price, ordinarily the volume you can sell goes down, and when you reduce the price, the volume you can sell goes up. Is that right? That's what you've learned?" They all nod yes. And I say, "Now tell me several instances when, if you want the physical volume to go up, the correct answer is to increase the price?" And there's this long and ghastly pause. And finally, in each of the two business schools in which I've tried this, maybe one person in fifty could name one instance. They come up with the idea that occasionally a higher price acts as a rough indicator of quality and thereby increases sales volumes.

This happened in the case of my friend Bill Ballhaus. When he was head of Beckman Instruments it produced some complicated product where if it failed it caused enormous damage to the purchaser. It wasn't a pump at the bottom of an oil well, but that's a good mental example. And he realized that the reason this thing was selling so poorly, even though it was better than anybody else's product, was because it was priced lower. It made people think it was a low quality gizmo. So he raised the price by 20% or so and the volume went way up.

But only one in fifty can come up with this sole instance in a modern business school – one of the business schools being Stanford, which is hard to get into. And nobody has yet come up with the main answer that I like. Suppose you raise that price, and use the extra money to bribe the other guy's purchasing agent? (Laughter). Is that going to work? And are there functional equivalents in economics – microeconomics – of raising the price and using the extra sales proceeds to drive sales higher? And of course there are zillion, once you've made that mental jump. It's so simple.

One of the most extreme examples is in the investment management field. Suppose you're the manager of a mutual fund, and you want to sell more. People commonly come to the following answer: You raise the commissions, which of course reduces the number of units of real investments delivered to the ultimate buyer, so you're increasing the price per unit of real investment that you're selling the ultimate customer. And you're using that extra commission to bribe the customer's purchasing agent. You're bribing the broker to betray his client and put the client's money into the high-commission product. This has worked to produce at least a trillion dollars of mutual fund sales.

This tactic is not an attractive part of human nature, and I want to tell you that I pretty completely avoided it in my life. I don't think it's necessary to spend your life selling what you would never buy. Even though it's legal, I don't think it's a good idea. But you shouldn't accept all my notions because you'll risk becoming unemployable. You shouldn't take my notions unless you're willing to risk being unemployable by all but a few.

I think my experience with my simple question is an example of how little synthesis people get, even in advanced academic settings, considering economic questions. Obvious questions, with such obvious answers. Yet people take four courses in economics, go to business school, have all these IQ points and write all these essays, but they can't synthesize worth a damn. This failure is not because the professors know all this stuff and they're deliberately withholding it from the students. This failure happens because the professors aren't all that good at this kind of synthesis. They were trained in a different way. I can't remember if it was Keynes or Galbraith who said that economics professors are most economical with ideas. They make a few they learned in graduate school last a lifetime.

Warren Buffett on Supply and Demand

Our second non-traditional commitment is in silver. Last year, we purchased 111.2 million ounces. Marked to market, that position produced a pre-tax gain of \$97.4 million for us in 1997. In a way, this is a return to the past for me: Thirty years ago, I bought silver because I anticipated its demonetization by the U.S. Government. Ever since, I have followed the metal's fundamentals but not owned it. In recent years, bullion inventories have fallen materially, and last summer Charlie and I concluded that a higher price would be needed to establish equilibrium between supply and demand. Inflation expectations, it should be noted, play no part in our calculation of silver's value.

In the 1978 shareholder letter, Buffett offered the following comment on supply and demand as it relates to commodity businesses earning a profit:

The textile industry illustrates in textbook style how producers of relatively undifferentiated goods in capital intensive businesses must earn inadequate returns except under conditions of tight supply or real shortage. As long as excess productive capacity exists, prices tend to reflect direct operating costs rather than capital employed. Such a supply-excess condition appears likely to prevail most of the time in the textile industry, and our expectations are for profits of relatively modest amounts in relation to capital.

In the 1982 annual letter to shareholders, Buffett wrote:

If, however, costs and prices are determined by full-bore competition, there is more than ample capacity, and the buyer cares little about whose product or distribution services he uses, industry economics are almost certain to be unexciting. They may well be disastrous.

Hence the constant struggle of every vendor to establish and emphasize special qualities of product or service. This works with candy bars (customers buy by brand name, not by asking for a "two-ounce candy bar") but doesn't work with sugar (how often do you hear, "I'll have a cup of coffee with cream and C & H sugar, please").

In many industries, differentiation simply can't be made meaningful. A few producers in such industries may consistently do well if they have a cost advantage that is both wide and sustainable. By definition such exceptions are few, and, in many industries, are non-existent. For the great majority of companies selling "commodity" products, a depressing equation of business economics prevails: persistent over-capacity without administered prices (or costs) equals poor profitability.

Of course, over-capacity may eventually self-correct, either as capacity shrinks or demand expands. Unfortunately for the participants, such corrections often are long delayed. When they finally occur, the rebound to prosperity frequently produces a pervasive enthusiasm for expansion that, within a few years, again creates over-capacity and a new profitless environment. In other words, nothing fails like success.

What finally determines levels of long-term profitability in such industries is the ratio of supply-tight to supply-ample years. Frequently that ratio is dismal. (It seems as if the most recent supply-tight period in our textile business – it occurred some years back – lasted the better part of a morning.)

In some industries, however, capacity-tight conditions can last a long time. Sometimes actual growth in demand will outrun forecasted growth for an extended period. In other cases, adding capacity requires very long lead times because complicated manufacturing facilities must be planned and built.

And In the 1991 letter, Buffett wrote:

In contrast, “a business” earns exceptional profits only if it is the low-cost operator or if supply of its product or service is tight. Tightness in supply usually does not last long. With superior management, a company may maintain its status as a low-cost operator for a much longer time, but even then unceasingly faces the possibility of competitive attack. And a business, unlike a franchise, can be killed by poor management.

2. Hindsight Bias: Why You're Not As Smart As You Think You Are

Hindsight bias occurs when we look backward in time and see events are more predictable than they were at the time a decision was made. This bias, also known as the “knew-it-all-along effect,” typically involves those annoying “*I told you so*” people who never really told you anything.

For instance, consider driving in the car with your partner and coming to a T in the road. Your partner decides to turn right and 4 miles down the road when you realize you are lost you think “I knew we should have taken that left.”

Hindsight bias can offer a number of benefits in the short run. For instance, it can be flattering to believe that our judgment is better than it actually is. And, of course, hindsight bias allows us to participate in one of our favorite pastimes — criticizing the decisions of others for their lack of foresight.

“Judgments about what is good and what is bad, what is worthwhile and what is a waste of talent, what is useful and what is less so, are judgments that seldom can be made in the present. They can safely be made only by posterity.”

— Tulvings

Aside from helping aid in a more objective reflection of decisions, hindsight bias also has several practical implications. For example, consider someone asked to review a paper but knows the results of the previous review from someone else? Or a physician asked for a second opinion after knowing the results of the first. The results of these actions will likely be biased by some degree. Once we know an outcome it becomes easy to find some plausible explanation.

Hindsight bias helps us become less accountable for our decisions, less critical of ourselves, and over-confident in our ability to make decisions.

One of the most interesting things I discovered when researching hindsight bias was the impact on our legal system and the perceptions of jurors.

* * *

Harvard Professor Max Bazerman offers:

The processes that give rise to anchoring and overconfidence are also at play with the hindsight bias. According to this explanation, knowledge of an event's outcome works as an anchor by which individuals interpret their prior judgments of the event's likelihood. Due to the selective accessibility of the confirmatory information during information retrieval, adjustments to anchors are inadequate. Consequently, hindsight knowledge biases our perceptions of what we remember knowing in foresight. Furthermore, to the extent that various pieces of data about the event vary in support of actual outcome, evidence that is consistent with the known outcome may become cognitively more salient and thus more available in memory. This tendency will lead an individual to justify a claimed foresight in view of “the facts provided.” Finally, the relevance of a particular piece of that may later be judged important to the extent to which it is representative of the final observed outcome.

In Cognitive Illusions, Rudiger Pohl offered the following explanations of hindsight bias: *Most prominent among the proposed explanations are cognitive accounts which assume that hindsight bias results from an inability to ignore the solution. Among the early approaches are the following three: (1) Fischhoff (1975) assumed an immediate and irreversible assimilation of the solution into one's knowledge base. As a consequence, the reconstructed estimate will be biased towards the solution. (2) Tversky and Kahneman (1974) proposed a cognitive heuristic for the anchoring effect, named anchoring and insufficient adjustment. The same mechanism may apply here, if the solution is assumed to serve as an “anchor” in the reconstruction process. The reconstruction starts from this anchor and is then adjusted in the direction of one's knowledge base. However, this adjustment process may stop too early, for example at the point where the first plausible value is reached, thus ending to a biased reconstruction. (3) Hell (1988) argued that the*

relative trace strengths of the regional estimate and of the solution might predict the amount of hindsight bias. The stronger the trace strength of the solution relative to that of the original estimate, the larger hindsight bias should be.

Pohl also offers an evolutionary explanation of hindsight bias:

Finally, some authors argued that hindsight bias is not necessarily a bothersome consequence of a “faulty” information process system, but that it may rather represent an unavoidable by-product of an evolutionary evolved function, namely adaptive learning. According to this view, hindsight bias is seen as the consequence of our most valuable ability to update previously held knowledge. This may be seen as a necessary process in order to prevent memory overload and thus to maintain normal cognitive functioning. Besides, updating allows us to keep our knowledge more coherent and to draw better inferences.

Ziva Junda, in social cognition, offers the following explanation of why hindsight bias occurs:

Preceding events take on new meaning and importance as they are made to cohere with the known outcome. Now that we know that our friends have filed for divorce, any ambiguous behavior we have seen is reinterpreted as indicative of tension, any disagreement gains significance, and any signs of affection seem irrelevant. It now seems obvious that their marriage was doomed from the start...Moreover, having adjusted our interpretations in light of current knowledge, it is difficult to imagine how things could have happened differently.

When making likelihood judgments, we often rely on the availability heuristic: The more difficult it is for us to imagine an outcome, the more unlikely it seems. Therefore, the difficulty we experience imagining how things might have turned out differently makes us all the more convinced that the outcomes that did occur were bound to have occurred.

Hindsight bias has large implications for criminal trials. In Jury Selection Hale Starr and Mark McCormick offer the following:

The effects of hindsight bias – which result in being held to a higher standard – are most critical for both criminal and civil defendants. The defense is more susceptible to the hindsight bias since their actions are generally the ones being evaluated for reasonableness in foresight-foreseeability. When jurors perceive that the results of particular actions were “reasonably” more likely after the outcome is known, defendants are judged as having been capable of knowing more than they knew at the time the action was taken and therefore as capable of preventing the “bad” outcome.

In post-verdict surveys jurors unknowingly demonstrate some of the effects of hindsight bias:

“I can’t understand why the managers didn’t try to get more information or use the information they had available. They should have known there would be safety problems at the plant”.

“The defendants should have known people would remove the safety shield around the tire. There should have been warnings so people wouldn’t do that”

“Even though he was a kid, he should have known that once he showed the others who had been drinking that he had a gun, things would get out of hand. He should have known guns invited violence.

Jurors influenced by the hindsight bias look at the evidence presented and determine that the defendants knew or should have known their actions were unsafe, unwise, or created a dangerous situation. Hindsight bias often results in the judgment that the event was “an accident or tragedy waiting to happen.”

* * *

Protection Against Hindsight Bias

In Principles of Forecasting, Jon Scott Armstrong, offers the following advice on how to protect yourself:

The surest protection against (hindsight bias) is disciplining ourselves to make explicit predictions, showing what we did in fact know (sounds like a decision journal). That record can also provide us with some protection against those individuals who are wont to second guess us, producing exaggerated claims of what we should have known (and perhaps should have told them). If these observers look to this record, it may show them that we are generally less proficient as forecaster than they would like while protecting us against charges of having blown a particular assignment. Having an explicit record can also protect us against overconfidence in our own forecasting ability: If we feel that we “knew all along” what was going to happen, then it is natural enough to think that we will have similar success in the future. Unfortunately, an exaggerated perception of a surprise-free past maybe portend a surprised-full future.

Documenting the reasons we made a forecast makes it possible for us to know not only how well the forecast did, but also where it went astray. For example, subsequent experiences may show that we used wrong (or misunderstood) inputs. In that case, we can, in principle, rerun the forecasting process with better inputs and assess the accuracy of our (retrospectively) revised forecasts. Perhaps we did have the right theory and procedures, but were applying them to a mistaken picture of then-current conditions...Of course inputs are also subject to hindsight bias, hence we need to record them explicitly as well. The essence of making sense out of outcome knowledge is reinterpreting the processes and conditions that produced the reported event.

3. Mental Model: Anchoring

We often pay attention to irrelevant information when making decisions.

One way this can play out is in the form of 'anchoring.' When we make an estimate, we can end up using irrelevant information as our 'anchor.' We then adjust from there, often failing to make sufficient updates.

Once we establish an anchor, we tend to focus on information which is consistent with it, ignoring information which is not. For example, when people buy houses, they tend to negotiate with the listed price as their starting point. Sellers tend to use the price they paid for the house as their starting point.

Anchoring is a fascinating psychological phenomenon. Experts and non-experts in a given area are affected by it alike. It can occur any time you need to give a numerical estimate. This can even affect those whose jobs are based on computing numerical figures, such as accountants.

* * *

Psychologists Amos Tversky and Daniel Kahneman first identified the concept of anchoring.

In one experiment, they asked participants to estimate the percentage of African nations which are members of the United Nations (UN.) One group was asked if the figure were greater or lower than 35%. Another group was asked if it were greater or lower than 65%. Participants in the first group gave much lower estimates. They used the number in their question as their anchor. Other studies have reproduced similar results.

The power of anchoring can be explained by the confirmation heuristic and by the limitations of our own mind. We selectively access hypothesis-consistent information without realizing it. Availability may also play a role in anchoring.

There are numerous examples of anchoring in everyday life:

- Children are tracked by schools that categorize them by ability at an early age and based on this initial "anchor" teachers derive expectations. Teachers tend to expect children assigned to the lower group to achieve little and have much higher expectations of children in the top group (for more info see Darley and Gross, 1983). Malcolm Gladwell talks more about anchoring in his book outliers.
- First impressions are a form of anchoring.
- Minimum payments on credit card bills.
- Posted interest rates at banks.
- Prices on a menu in restaurants.

* * *

Heuristic and Biases: The Psychology of Intuitive Judgment offers:

"To examine this heuristic, Tversky and Kahneman (1974) developed a paradigm in which participants are given an irrelevant number and asked if the answer to the question is greater or less than that value. After this comparative assessment, participants provide an absolute answer. Countless experiments have shown that people's absolute answers are influenced by initial comparison with the irrelevant anchor. People estimate that Gandhi lived to be roughly 67 years old, for example, if they first decided whether he died before or after the age of 140, but only 50 years old if they first decided whether he died before or after the age of 9.

Anchoring effects have traditionally been interpreted as a result of insufficient adjustment from an irrelevant value, but recent evidence casts doubt on this account. Instead, anchoring effects observed in the standard paradigm appear to be produced by the increased accessibility of anchor consistent information.

* * *

In Judgment and Decision Making, David Hardman says:

Anchoring effects have been observed in a variety of domains including pricing, negotiation, legal judgment, lotteries and gambles, probability estimates, and general knowledge. In one of these studies, Northcraft and Neale (1987) demonstrated anchoring effects in the pricing estimates of estate agents...

Despite the robustness of the anchoring effect, there has been little agreement as to the true nature of the underlying processes. One theory that has been proposed is that of selective anchoring (Mussweiler and Strack, 1997). According to this account, the comparative question task activates information into memory that is subsequently more accessible when making an absolute judgment...

Epley (2004) listed four findings that are consistent with the selective memory account: (1) People attend to shared features between the anchor and target more than to unique features; (2) Completion of a standard anchoring task speeds identification of words consistent with implications of an anchor value rather than words inconsistent with it; (3) The size of anchoring effects can be influenced by altering the hypothesis tested in the comparative assessment (for example, asking whether the anchor is less than a target value has a different effect to asking whether it is more than a target value); (4) People with greater domain knowledge are less susceptible to the effects of irrelevant anchors.

** * **

In Fooled by Randomness, Nicholas Taleb writes:

Anchoring to a number is the reason people do not react to their total wealth, but rather to differences of wealth from whatever number they are currently anchored to. This is in major conflict with economic theory, as according to economists, someone with \$1 million in the bank would be more satisfied than if he had \$500 thousand but this is not necessarily the case.

** * **

Tversky and Kahneman (1974)

In many situations, people make estimates by starting from an initial value that is adjusted to yield the final answer. The initial value, or starting point, may be suggested by the formulation of the problem, or it may be the result of a partial computation. In either case, adjustments are typically insufficient (Slovic & Lichtenstein, 1971). That is, different starting points yield different estimates, which are biased toward the initial values. We call this phenomenon anchoring.

** * **

Russell Fuller writes:

Psychologists have documented that when people make quantitative estimates, their estimates may be heavily influenced by previous values of the item. For example, it is not an accident that a used car salesman always starts negotiating with a high price and then works down. The salesman is trying to get the consumer anchored on the high price so that when he offers a lower price, the consumer will estimate that the lower price represents a good value. Anchoring can cause investors to under-react to new information.

4. Social Proof: Why We Look to Others For What We Should Think and Do

"Where all think alike, no one thinks very much."

— Walter Lippmann

"The five most dangerous words in business are: 'Everybody else is doing it.'"

— Warren Buffett

The Basics

Consider a university freshman, attempting to navigate the adult world for the first time. They are convinced that all the other students around them somehow know more about adulthood. Perhaps they imagine that everyone else was handed a manual they somehow missed. Everyone else seems to know where to go, how to make new friends, what to do. Except, of course, the majority of their peers feel equally unsure and are doing the exact same. We never quite leave behind that tendency to look at others for clues.

When we feel uncertain, we all tend to look to others for answers as to how we should behave, what we should think and what we should do. This psychological concept is known as social proof. It occurs as a result of our natural desire to behave in the correct manner and fit in with others. It can be easy to assume that everyone else has a better grasp of what to do in a given situation. Social proof is especially prevalent in ambiguous or unfamiliar conditions, or in big groups. It affects us both in public and in private.

In The Power of Positive Deviance, Richard Pascale explains social proof:

A well-known principle of chemistry establishes that active ingredients can be mixed together with little effect until a third ingredient- often an innocuous catalyst- triggers a chemical synthesis. Analogously, the social system is the catalyst between all the stuff we know versus what actually alters our behavior and mental maps. Social proof? Simple idea, really: it boils down to 'seeing is believing.'... We use social proof to decide how to dispose of an empty popcorn box in a movie theater, how fast to drive on a highway, or whether to tackle that fried chicken or corn on the cob with our hands at a dinner party. At the more consequential end of the spectrum, we rely on social proof to inform moral choices- whether to assist an inebriated football enthusiast who falls on the sidewalk or step forward as a whistleblower.

Social proof can be problematic for two main reasons. Firstly, groups of people can reach conclusions which are suboptimal or even outright wrong. This is also known as groupthink or herd behavior. Secondly, social proof can be manipulated to guide us towards choices we would not otherwise make. In extreme cases, it can lead to groups of people becoming violent or antisocial. We will look at one of the worst examples further on in this post.

No one likes to be confused about what to do in a situation where other people are around to witness any blunders. The more uncertain we feel, the more susceptible we are to social proof.

A further key factor is the similarity we see between ourselves and the people around us.

When people relate to those around them (due to gender, class, race, shared interests, and other commonalities) they mimic each other's behavior with greater care. This is known as implicit egotism and linked to the mirror neurons in our brains.

In Private Truths, Public Lies, Timur Kuran writes of the influence on social proof on groups:

A phrase like 'the American way' when uttered on behalf of a particular agenda, signals that most Americans, or at least most respectable Americans agree on what is appropriate. Of course, the claim embodied in such a phrase may harbor much exaggeration. Other methods of exaggeration include dwelling on biased polls [e.g. a political poll only completed by white males] and overstating the size of a demonstration. All such methods constitute direct appeals to social proof. ...the softness or hardness of a belief must not be confused with its power, which is its potential influence over behaviour. A belief based

solely on social proof -one that is extremely soft- may generate wild passions, as when a student participates fervently in a revolutionary movement whose program she has never read. By the same token, a belief formed through extensive personal experience- one that is very hard may elicit little action. An educator convinced that schools are in decline will not necessarily act on this information fearing objections.

No matter how individual we think we are, we all have an inherent desire to conform. Psychologists call this the bandwagon effect- ideas, beliefs, trends, and concepts are spread between people. The more people adopt them, the more people are influenced to do so.

In The Negotiator's Fieldbook, an example of how social proof is used by lawyers is provided:

A lawyer... might exhibit certain behaviors at the bargaining table (e.g. she can attempt to frame the negotiation as a search for jointly desirable outcomes) and thereby model the behaviour for her counterpart. This, in turn, could induce her counterpart to conduct herself in a similar manner. Likewise, a lawyer might use evidence from similar cases...showing how often- even perhaps for what amounts- litigants in similar cases have settled. By demonstrating that similarly situated others have settled, the lawyer may be able to persuade her counterpart that settlement is appropriate for her as well.

Robert Cialdini and the Science of Persuasion

According to Robert Cialdini, social proof is one of the six key principles of persuasion.

When combined with reciprocity, consistency, authority, liking, and scarcity, it can be used to influence people's actions.

In one study, researchers from New York City university planted a man on a busy sidewalk. Amongst crowds of people, he stopped and looked upwards for a minute. The experiment by social psychologists Milgram, Bickman, and Berkowitz was designed to test the power of social proof. When just one man gazed at the sky, just 4% of passersby also looked up. When the experiment was repeated with five men looking upwards, 18% of passersby followed suit, and for 15 the figure was 40%. This experiment is cited by Cialdini as an illustration of how social proof persuades people to behave in certain ways.

Another study cited by Cialdini concerned charitable donations, finding that showing people a list of their neighbors who had donated to a charity led to a substantial increase in funds raised. The more names on the list, the more people donated. Cialdini also explains how the use of social proof can backfire. Campaigns to reduce drug and alcohol consumption which cite high rates of abuse can have the opposite effect. People subconsciously seek to comply with the many others who are engaging in this behavior. Cialdini writes:

The principle of social proof says so: The greater the number of people who find any idea correct, the more the idea will be correct...We will use the actions of others to decide on proper behavior for ourselves, especially when we view those others as similar to ourselves...When we are uncertain, we are willing to place an enormous amount of trust in the collective knowledge of the crowd...First, we seem to assume that if a lot of people are doing the same thing, they must know something we don't...Social proof is most powerful for those who feel unfamiliar or unsure in a specific situation and who, consequently, must look outside themselves for evidence of how best to behave there... Since 95 percent of the people are imitators and only 5 percent initiators, people are persuaded more by the actions of others than by any proof we can offer.

Examples of social proof

"Lack of skepticism is often the result of our social beliefs. No one would believe such absurd nonsense as a moon made of cheese or a flying teapot when it is proposed in such an unfamiliar way. However, when we encounter equally absurd belief systems in socially or historically-familiar contexts, they seem to have a measure of proof and be established or valid. In other words, a lot of people believing some total bullshit creates a form of social

proof.”

— *Sia Mohajer*

An unfortunate fact of life is that some people desperately seek opportunities, while others are bombarded with them. One person struggles to find a job, sending their CV everywhere. Another person has an impressive role already and yet is constantly offered others. One book proposal is fought over by publishers. Another is relegated straight to the bin. One person never manages to find anyone willing to go on a date, while another receives non-stop propositions despite being in a relationship. Why does this happen? The answer is social proof.

When someone is regarded as successful, talented, or attractive that view spreads. When social proof is absent, others are more dismissive and attentive to flaws. Two people could be equally qualified, but the one with a high-ranking job already seems like a fail-safe choice for a key role. Two writers could be equally talented, but the one whose previous book was a bestseller will have much less trouble getting their next published. And so on.

The Arizona Petrified Forest

A classic example of social proof occurred in the Arizona Petrified Forest. The theft of unusual petrified wood by visitors was becoming a serious issue, depleting the ancient woodland. Staff put up a sign stating: ‘Many past visitors have removed the petrified wood from the park, destroying the natural state of the Petrified Forest.’ This was intended to deter theft, but it had the opposite effect. The depletion of the petrified wood tripled. Experts who looked at the case determined that the signs had served as social proof, making people feel the act was justified.

Claquers

Another example of social proof is a *claque*. A *claque* is a group of professional applauders, positioned in theaters or opera houses. *Claqueurs* (members of a *claque*) have been used since Emperor Nero, whose performances were applauded by five thousand soldiers. In the 16th century, *claqueurs* became a common part of theater and opera performances. Their job was to applaud a performance, encouraging others to do the same. Social proof meant that once a few people began to applaud, the rest did the same. Audience members saw that others appeared to enjoy the piece and went away with a more positive view of it. Whilst *clacquers* are now rare, their existence shows how social proof can distort reality.

The Jonestown Massacre

The 1978 Jonestown Massacre is one of the most shocking, terrifying examples of the dark side of social proof. Under the leadership of religious fanatic Jim Jones, 918 people died in a commune in Georgetown. Although the event was technically a mass suicide, the degree of duress and force under which the deaths happened and the fact that 1 in 3 were minors mean that massacre is more accurate. Nearly a thousand members of the cult drank poison, including infants. Within a matter of minutes, all were dead.

In the aftermath of this tragedy (the worst loss of American lives on a single occasion until 9/11), the world struggled to make sense of how it could have happened. One important element which emerged upon study was that of social proof. Isolated from the rest of the world, the commune had no outside influences and no one to emulate save each other. At the head of the cult was the self-appointed messiah Jim Jones who manipulated and controlled his followers. Force was used to squash any dissent, meaning people had no option but to comply. Cult members were encouraged to inform Jones of anyone who felt rebellious, and families were broken up to give him total control. If someone did object, they had no allies to side with and reinforce their change of heart. The few people who survived were mostly couples who managed to stay together and had the social proof provided by each other necessary to retain their opinions. Deborah Blakey, a survivor later said:

Any disagreement with [Jones'] dictates came to be regarded as "treason."Although I felt terrible about what was happening, I was afraid to say anything because I knew that anyone with a differing opinion gained the wrath of Jones and other members.

Jones' final, harrowing speech which manipulated his followers into committing suicide can be heard here. It provides a clear example of how people succumbed to social proof.

Throughout the tape, a number of people are heard dissenting, only to be forced back into submission by their peers.

How marketers use social proof

*"Social proof is a flame to the human mind moth,
and it leaves a fire trail of destruction across the path of enough."*

— Will Jelbert (The Happiness Animal)

Marketers love using social proof to encourage people to spend more money. If you ever feel the strange urge to buy something you don't need, this could be down to social proof.

Marketers achieve this in a number of ways:

- Using influencers and famous people. A phenomenon known by psychologists as the 'halo and horns effect' means we see a product/service as more desirable if it is associated with someone we like. On a subconscious level, we imagine their good qualities rubbing off on the item advertised. Likewise, if we wish to be like someone, we may think anything they endorse will make us more like them.
- Implying popularity. Night clubs and bars often make patrons wait outside, even when the venues are not full. This creates an aura of desirability
- Reviews/ratings. 70% of people look at these before making a purchase, to see what others think about a product or service. Even though these can be biased, anecdotal or even fake, we judge people 'like us' as more trustworthy than the companies. For example, if someone is planning on buying a certain vacuum cleaner, just one negative review can sway them away from it- never mind that said reviewer may have used it incorrectly.

Social proof is part of the Farnam Street latticework of mental models. To read more on the topic look to Cialdini's Persuasion, Gladwell's Tipping Point, or Kuran's Private Truths, Public Lies.

5. Mental Models: The Best Way to Make Intelligent Decisions (~100 Models Explained)

What Are Mental Models?

A mental model is a compression of how something works. Any idea, belief, or concept can be distilled down. Like a map, mental models reveal key information while ignoring irrelevant details. Models concentrate the world into understandable and useable chunks. Mental models help us understand the world. For example, velocity is a mental model that helps you understand that both speed and direction matter. Reciprocity is a mental model that helps you understand how going positive and going first gets the world to do most of the work for you. Margin of Safety is a mental model that helps you understand that things don't always go as planned. Relativity is a mental model that shows us we have blind spots and how a different perspective can reveal new information. The list goes on.

Eliminating Blind Spots

In life and business, the person with the fewest blind spots wins.

The source of all poor choices is blind spots. Think about it. If you had perfect information, you would always make the best decision. You'd play your hand perfectly in a poker game where you could see everyone's cards. You wouldn't make any mistakes.

How do we eliminate blind spots?

The best way to reduce our blind spots is to change our perspective. Just as knowing where to stand can turn a good photo into a great one, changing your perspective on a situation reveals critical information and offers new solutions.

Think of each model as a lens through which you can see the world. Each lens offers a different perspective, revealing new information. Looking through one lens lets you see one thing, and looking through another reveals something different. Looking through them both reveals more than each one individually.

While there are a lot of specific mental models, only a handful of general ones come from the big disciplines. Understanding them positions you to make fewer errors, see things others miss, and take better actions.

Let's take a look at the best general models.

You've got to have models in your head and you've got to array your experience – both vicarious and direct – onto this latticework of mental models.

Charlie munger

A Latticework of Mental Models

Worldly wisdom is not simply memorizing things and repeating them back. The people that do that fail at work and fail in life. Wisdom is knowing the consequences of your actions, which comes from the alignment between facts and reasoning.

The world is not divided into distinct disciplines. For example, business professors won't discuss physics in their lectures, but they should. Velocity teaches us that speed and direction matter. Kinetic energy teaches us that velocity matters more than mass when creating a force. Understanding these insights helps you outperform.

In the real world, everything is connected like a latticework. Just because our teachers didn't show us how to use the big ideas from all the disciplines in life and business doesn't mean we can't learn them ourselves. That's why we created *The Great Mental Models* project.

Here are the big ideas that can help you make better decisions, avoid problems, and spot opportunities others miss.

- Core Thinking Concepts
- Physics and Chemistry
- Biology
- Systems
- Numeracy
- Microeconomics
- Military and War
- Human Nature and Judgment

The Core Mental Models

1. The Map is Not the Territory

The map of reality is not reality. Even the best maps are imperfect. That's because they are reductions of what they represent. If a map were to represent the territory with perfect fidelity, it would no longer be a reduction and thus would no longer be useful to us. A map can also be a snapshot of a point in time, representing something that no longer exists. This is important to keep in mind as we think through problems and make better decisions.

2. Circle of Competence

When ego and not competence drive what we undertake, we have massive blind spots. If you know what you understand, you know where you have an edge over others. When you are honest about where your knowledge is lacking, you know where you are vulnerable and where you can improve. Understanding your circle of competence improves decision-making and outcomes.

3. First Principles Thinking

First-principles thinking is one of the best ways to reverse-engineer complicated situations and unleash creative possibility. Sometimes called reasoning from first principles, it's a tool to help clarify complicated problems by separating the underlying ideas or facts from any assumptions based on them. What remains are the essentials. If you know the first principles of something, you can build the rest of your knowledge around them to produce something new.

4. Thought Experiment

Thought experiments can be defined as "devices of the imagination used to investigate the nature of things." Many disciplines, such as philosophy and physics, make use of thought experiments to examine what can be known. In doing so, they can open up new avenues for inquiry and exploration. Thought experiments are powerful because they help us learn from our mistakes and avoid future ones. They let us take on the impossible, evaluate the potential consequences of our actions, and re-examine history to make better decisions. They can help us both figure out what we really want and the best way to get there.

5. Second-Order Thinking

Almost everyone can anticipate the immediate results of their actions. This type of first-order thinking is easy and safe, but it's also a way to ensure you get the same results that everyone else gets. Second-order thinking is thinking farther ahead and thinking holistically. It requires us to consider not only our actions and their immediate consequences but the subsequent effects of those actions as well. Failing to consider the second and third-order effects can unleash disaster.

6. Probabilistic Thinking

Probabilistic thinking is essentially trying to estimate, using some tools of math and logic, the likelihood of any specific outcome coming to pass. It is one of the best tools we have to improve the accuracy of our decisions. In a world where each moment is determined by an infinitely complex set of factors, probabilistic thinking helps us identify the most likely outcomes. When we know these, our decisions can be more precise and effective.

7. Inversion

Inversion is a powerful tool to improve your thinking because it helps you identify and remove obstacles to success. The root of inversion is “invert,” which means to upend or turn upside down. As a thinking tool, it means approaching a situation from the opposite end of the natural starting point. Most of us tend to think one way about a problem: forward. Inversion allows us to flip the problem around and think backward. Sometimes it’s good to start at the beginning, but it can be more useful to start at the end.

8. Occam’s Razor

Simpler explanations are more likely to be true than complicated ones. This is the essence of Occam’s Razor, a classic principle of logic and problem-solving. Instead of wasting your time trying to disprove complex scenarios, you can make decisions more confidently by basing them on the explanation that has the fewest moving parts.

9. Hanlon’s Razor

Hard to trace in its origin, Hanlon’s Razor states that we should not attribute to malice that which is more easily explained by stupidity. In a complex world, using this model helps us avoid paranoia and ideology. By not generally assuming that bad results are the fault of a bad actor, we look for options instead of missing opportunities. This model reminds us that people do make mistakes. It demands that we ask if there is another reasonable explanation for the events that have occurred. The explanation most likely to be right is the one that contains the least amount of intent.

The Mental Models of Physics and Chemistry

1. Relativity

Relativity has been used in several contexts in the world of physics, but the important aspect to study is the idea that an observer cannot truly understand a system of which he himself is a part. For example, a man inside an airplane does not feel like he is experiencing movement, but an outside observer can see that movement is occurring. This form of relativity tends to affect social systems in a similar way.

2. Reciprocity

If I push on a wall, physics tells me that the wall pushes back with equivalent force. In a biological system, if one individual acts on another, the action will tend to be reciprocated in kind. And of course, human beings act with intense reciprocity demonstrated as well.

3. Thermodynamics

The laws of thermodynamics describe energy in a closed system. The laws cannot be escaped and underlie the physical world. They describe a world in which useful energy is constantly being lost, and energy cannot be created or destroyed. Applying their lessons to the social world can be a profitable enterprise.

4. Inertia

An object in motion with a certain vector wants to continue moving in that direction unless acted upon. This is a fundamental physical principle of motion; however, individuals, systems, and organizations display the same effect. It allows them to minimize the use of energy, but can cause them to be destroyed or eroded.

5. Friction and Viscosity

Both friction and viscosity describe the difficulty of movement. Friction is a force that opposes the movement of objects that are in contact with each other, and viscosity measures how hard it is for one fluid to slide over another. Higher viscosity leads to higher resistance. These concepts teach us a lot about how our environment can impede our movement.

6. Velocity

Velocity is not equivalent to speed; the two are sometimes confused. Velocity is speed plus vector: how fast something gets somewhere. An object that moves two steps forward and then two steps back has moved at a certain speed but shows no velocity. The addition of the vector, that critical distinction, is what we should consider in practical life.

7. Leverage

Most of the engineering marvels of the world were accomplished with applied leverage. As famously stated by Archimedes, "Give me a lever long enough and I shall move the world." With a small amount of input force, we can make a great output force through leverage. Understanding where we can apply this model to the human world can be a source of great success.

8. Activation Energy

A fire is not much more than a combination of carbon and oxygen, but the forests and coal mines of the world are not combusting at will because such a chemical reaction requires the input of a critical level of "activation energy" to get a reaction started. Two combustible elements alone are not enough.

9. Catalysts

A catalyst either kick-starts or maintains a chemical reaction but isn't itself a reactant. The reaction may slow or stop without the addition of catalysts. Social systems, of course, take on many similar traits, and we can view catalysts in a similar light.

10. Alloying

When we combine various elements, we create new substances. This is no great surprise, but what can be surprising in the alloying process is that $2+2$ can equal not 4 but 6 – the alloy can be far stronger than the simple addition of the underlying elements would lead us to believe. This process leads us to engineer great physical objects, but we understand many intangibles in the same way; a combination of the right elements in social systems or even individuals can create a $2+2=6$ effect similar to alloying.

The Mental Models of Biology

1. Evolution Part One: Natural Selection and Extinction

Evolution by natural selection was once called “the greatest idea anyone ever had.” In the 19th century, Charles Darwin and Alfred Russel Wallace simultaneously realized that species evolve through random mutation and differential survival rates. If we call human intervention in animal breeding an example of “artificial selection,” we can call Mother Nature deciding the success or failure of a particular mutation “natural selection.” Those best suited for survival tend to be preserved. But of course, conditions change.

2. Evolution Part Two: Adaptation and The Red Queen Effect

Species tend to adapt to their surroundings in order to survive, given the combination of their genetics and their environment – an always-unavoidable combination. However, adaptations made in an individual’s lifetime are not passed down genetically, as was once thought: *Populations* of species adapt through the process of evolution by natural selection, as the most-fit examples of the species replicate at an above-average rate. The evolution-by-natural-selection model leads to something of an arms race among species competing for limited resources. When one species evolves an advantageous adaptation, a competing species must respond in kind or fail as a species. Standing still can mean falling behind. This arms race is called the Red Queen Effect for the character in *Alice in Wonderland* who said, “Now, here, you see, it takes all the running you can do, to keep in the same place.”

3. Ecosystems

An ecosystem describes any group of organisms coexisting with the natural world. Most ecosystems show diverse forms of life taking on different approaches to survival, with such pressures leading to varying behavior. Social systems can be seen in the same light as the physical ecosystems and many of the same conclusions can be made.

4. Niches

Most organisms find a niche: a method of competing and behaving for survival. Usually, a species will select a niche for which it is best adapted. The danger arises when multiple species begin competing for the same niche, which can cause an extinction – there can be only so many species doing the same thing before limited resources give out.

5. Self-Preservation

Without a strong self-preservation instinct in an organism’s DNA, it would tend to disappear over time, thus eliminating that DNA. While cooperation is another important model, the self-preservation instinct is strong in all organisms and can cause violent, erratic, and/or destructive behavior for those around them.

6. Replication

A fundamental building block of diverse biological life is high-fidelity replication. The fundamental unit of replication seems to be the DNA molecule, which provides a blueprint for the offspring to be built from physical building blocks. There are a variety of replication methods, but most can be lumped into sexual and asexual.

7. Cooperation

Competition tends to describe most biological systems, but cooperation at various levels is just as important a dynamic. In fact, the cooperation of a bacterium and a simple cell probably created the first complex cell and all of the life we see around us. Without cooperation, no group survives, and the cooperation of groups gives rise to even more complex versions of organization. Cooperation and competition tend to coexist at multiple levels.

The Prisoner's Dilemma is a famous application of game theory in which two prisoners are both better off cooperating with each other, but if one of them cheats, the other is better off cheating. Thus the dilemma. This model shows up in economic life, in war, and in many other areas of practical human life. Though the prisoner's dilemma theoretically leads to a poor result, in the real world, cooperation is nearly always possible and must be explored.

8. Hierarchical Organization

Most complex biological organisms have an innate feel for how they should organize. While not all of them end up in hierarchical structures, many do, especially in the animal kingdom. Human beings like to think they are outside of this, but they feel the hierarchical instinct as strongly as any other organism. This includes the Stanford Prison Experiment and Milgram Experiments, which demonstrated what humans learned practically many years before: the human bias towards being influenced by authority. In a dominance hierarchy such as ours, we tend to look to the leader for guidance on behavior, especially in situations of stress or uncertainty. Thus, authority figures have a responsibility to act well, whether they like it or not.

9. Incentives

All creatures respond to incentives to keep themselves alive. This is the basic insight of biology. Constant incentives will tend to cause a biological entity to have constant behavior to an extent. Humans are included and are particularly great examples of the incentive-driven nature of biology; however, humans are complicated in that their incentives can be hidden or intangible. The rule of life is to repeat what works and has been rewarded.

10. Tendency to Minimize Energy Output (Mental and physical)

In a physical world governed by thermodynamics and competition for limited energy and resources, any biological organism that was wasteful with energy would be at a severe disadvantage for survival. Thus, we see in most instances that behavior is governed by a tendency to minimize energy usage when at all possible.

The Mental Models of Systems Thinking

1. Feedback Loops

All complex systems are subject to positive and negative feedback loops whereby A causes B, which in turn influences A (and C), and so on – with higher-order effects frequently resulting from the continual movement of the loop. In a homeostatic system, a change in A is often brought back into line by an opposite change in B to maintain the balance of the system, as with the temperature of the human body or the behavior of an organizational culture. Automatic feedback loops maintain a “static” environment unless and until an outside force changes the loop. A “runaway feedback loop” describes a situation in which the output of a reaction becomes its own catalyst (auto-catalysis).

2. Equilibrium

Homeostasis is the process through which systems self-regulate to maintain an equilibrium state that enables them to function in a changing environment. Most of the time, they over or undershoot it by a little and must keep adjusting. Like a pilot flying a plane, the system is off course more often than on course. Everything within a homeostatic system contributes to keeping it within a range of equilibrium, so it is important to understand the limits of the range.

3. Bottlenecks

A bottleneck describes the place at which a flow (of a tangible or intangible) is stopped, thus constraining it from continuous movement. As with a clogged artery or a blocked drain, a bottleneck in the production of any good or service can be small but have a disproportionate impact if it is in the critical path. However, bottlenecks can also be a source of inspiration as they force us to reconsider if there are alternate pathways to success.

4. Scale

One of the most important principles of systems is that they are sensitive to scale. Properties (or behaviors) tend to change when you scale them up or down. In studying complex systems, we must always be roughly quantifying – in orders of magnitude, at least – the scale at which we are observing, analyzing, or predicting the system.

5. Margin of Safety

Similarly, engineers have also developed the habit of adding a margin for error into all calculations. In an unknown world, driving a 9,500-pound bus over a bridge built to hold precisely 9,600 pounds is rarely seen as intelligent. Thus, on the whole, few modern bridges ever fail. In practical life outside of physical engineering, we can often profitably give ourselves margins as robust as the bridge system.

6. Churn

Insurance companies and subscription services are well aware of the concept of churn – every year, a certain number of customers are lost and must be replaced. Standing still is the equivalent of losing, as seen in the model called the “Red Queen Effect.” Churn is present in many business and human systems: A constant figure is periodically lost and must be replaced before any new figures are added over the top.

7. Algorithms

While hard to precisely define, an algorithm is generally an automated set of rules or a “blueprint” leading a series of steps or actions resulting in a desired outcome, and often stated in the form of a series of “If → Then” statements. Algorithms are best known for their use in modern computing, but are a feature of biological life as well. For example, human DNA contains an algorithm for building a human being.

8. Critical mass

A system becomes critical when it is about to jump discretely from one phase to another. The marginal utility of the last unit before the phase change is wildly higher than any unit before it. A frequently cited example is water turning from a liquid to a vapor when heated to a specific temperature. “Critical mass” refers to the mass needed to have the critical event occur, most commonly in a nuclear system.

9. Emergence

Higher-level behavior tends to emerge from the interaction of lower-order components. The result is frequently not linear – not a matter of simple addition – but rather non-linear, or exponential. An important resulting property of emergent behavior is that it cannot be predicted from simply studying the component parts.

10. Irreducibility

We find that in most systems there are irreducible quantitative properties, such as complexity, minimums, time, and length. Below the irreducible level, the desired result simply does not occur. One cannot get several women pregnant to reduce the amount of time needed to have one child, and one cannot reduce a successfully built automobile to a single part. These results are, to a defined point, irreducible.

11. Law of Diminishing Returns

Related to scale, most important real-world results are subject to an eventual decrease of incremental value. A good example would be a poor family: Give them enough money to thrive, and they are no longer poor. But after a certain point, additional money will not improve their lot; there is a clear diminishing return of additional dollars at some roughly quantifiable point. Often, the law of diminishing returns veers into negative territory – i.e., receiving too much money could destroy the poor family.

The Mental Models of Numeracy

1. Distributions

The normal distribution is a statistical process that leads to the well-known graphical representation of a bell curve, with a meaningful central “average” and increasingly rare standard deviations from that average when correctly sampled. (The so-called “central limit” theorem.) Well-known examples include human height and weight, but it’s just as important to note that many common processes, especially in non-tangible systems like social systems, do not follow this pattern. Normal distributions can be contrasted with power law, or exponential, distributions.

2. Compounding

It’s been said that Einstein called compounding a wonder of the world. He probably didn’t, but it is a wonder. Compounding is the process by which we add interest to a fixed sum, which then earns interest on the previous sum *and* the newly added interest, and then earns interest on that amount, and so on *ad infinitum*. It is an *exponential* effect, rather than a linear, or additive, effect. Money is not the only thing that compounds; ideas and relationships do as well. In tangible realms, compounding is always subject to physical limits and diminishing returns; intangibles can compound more freely. Compounding also leads to the time value of money, which underlies all of modern finance.

3. Sampling

When we want to get information about a population (meaning a set of alike people, things, or events), we usually need to look at a sample (meaning a part of the population). It is usually not possible or even desirable to consider the entire population, so we aim for a sample that represents the whole. As a rule of thumb, more measurements mean more accurate results, all else being equal. Small sample sizes can produce skewed results.

4. Randomness

Though the human brain has trouble comprehending it, much of the world is composed of random, non-sequential, non-ordered events. We are “fooled” by random effects when we attribute causality to things that are actually outside of our control. If we don’t course-correct for this fooled-by-randomness effect – our faulty sense of pattern-seeking – we will tend to see things as being more predictable than they are and act accordingly.

5. Regression to the Mean

In a normally distributed system, long deviations from the average will tend to return to that average with an increasing number of observations: the so-called Law of Large Numbers. We are often fooled by regression to the mean, as with a sick patient improving spontaneously around the same time they begin taking an herbal remedy, or a poorly performing sports team going on a winning streak. We must be careful not to confuse statistically likely events with causal ones.

6. Multiplying by Zero

Any reasonably educated person knows that any number multiplied by zero, no matter how large the number, is still zero. This is true in human systems as well as mathematical ones. In some systems, a failure in one area can negate great effort in all other areas. As simple multiplication would show, fixing the “zero” often has a much greater effect than does trying to enlarge the other areas.

7. Equivalence

The introduction of algebra allowed us to demonstrate mathematically and abstractly that two seemingly different things could be the same. By manipulating symbols, we can demonstrate equivalence or inequivalence, the use of which led humanity to untold engineering and technical abilities. Knowing at least the basics of algebra can allow us to understand a variety of important results.

8. Surface Area

The surface area of a three dimensional object is the amount of space on the outside of it. Thus, the more surface area you have, the more contact you have with your environment. Sometimes a high surface area is desirable: Our lungs and intestines have a huge surface area to increase the absorption of oxygen and nutrients. Other times we want to reduce our exposure, such as limiting our internet exposure to reduce the attack surface.

9. Global and Local Maxima

The maxima and minima of a mathematical function are the largest and smallest values over its domain. Although there is one maximum value, the global maximum, there can be smaller peaks of value in a given range, the local maxima. Global and local maxima help us identify peaks, and if there is still potential to go higher or lower. It also reminds us that sometimes we have to go down to go back up.

The Mental Models of Microeconomics

1. Opportunity Costs

Doing one thing means not being able to do another. We live in a world of trade-offs, and the concept of opportunity cost rules all. Most aptly summarized as “there is no such thing as a free lunch.”

2. Creative Destruction

Coined by economist Joseph Schumpeter, the term “creative destruction” describes the capitalistic process at work in a functioning free-market system. Motivated by personal incentives (including but not limited to financial profit), entrepreneurs will push to best one another in a never-ending game of creative one-upmanship, in the process destroying old ideas and replacing them with newer technology. Beware getting left behind.

3. Comparative Advantage

The Scottish economist David Ricardo had an unusual and non-intuitive insight: Two individuals, firms, or countries could benefit from trading with one another even if one of them was better at everything. Comparative advantage is best seen as an applied opportunity cost: If it has the opportunity to trade, an entity gives up free gains in productivity by not focusing on what it does best.

4. Specialization (Pin Factory)

Another Scottish economist, Adam Smith, highlighted the advantages gained in a free-market system by specialization. Rather than having a group of workers each producing an entire item from start to finish, Smith explained that it's usually far more productive to have each of them specialize in one aspect of production. He also cautioned, however, that each worker might not enjoy such a life; this is a trade-off of the specialization model.

5. Seizing the Middle

In chess, the winning strategy is usually to seize control of the middle of the board, so as to maximize the potential moves that can be made and control the movement of the maximal number of pieces. The same strategy works profitably in business, as can be demonstrated by John D. Rockefeller's control of the refinery business in the early days of the oil trade and Microsoft's control of the operating system in the early days of the software trade.

6. Trademarks, Patents, and Copyrights

These three concepts, along with other related ones, protect the creative work produced by enterprising individuals, thus creating additional incentives for creativity and promoting the creative-destruction model of capitalism. Without these protections, information and creative workers have no defense against their work being freely distributed.

7. Double-Entry Bookkeeping

One of the marvels of modern capitalism has been the bookkeeping system introduced in Genoa in the 14th century. The double-entry system requires that every entry, such as income, also be entered into another corresponding account. Correct double-entry bookkeeping acts as a check on potential accounting errors and allows for accurate records and thus, more accurate behavior by the owner of a firm.

8. Utility (Marginal, Diminishing, Increasing)

The usefulness of additional units of any good tends to vary with scale. Marginal utility allows us to understand the value of one additional unit, and in most practical areas of life, that utility diminishes at some point. On the other hand, in some cases, additional units are subject to a “critical point” where the utility function jumps discretely up or down. As an example, giving water to a thirsty man has diminishing marginal utility with each additional unit, and can eventually kill him with enough units.

9. Bribery

Often ignored in mainstream economics, the concept of bribery is central to human systems: Given the chance, it is often easier to pay a certain agent to look the other way than to follow the rules. The enforcer of the rules is then neutralized. This principal/agent problem can be seen as a form of arbitrage.

10. Arbitrage

Given two markets selling an identical good, an arbitrage exists if the good can profitably be bought in one market and sold at a profit in the other. This model is simple on its face, but can present itself in disguised forms: The only gas station in a 50-mile radius is also an arbitrage as it can buy gasoline and sell it at the desired profit (temporarily) without interference. Nearly all arbitrage situations eventually disappear as they are discovered and exploited.

11. Supply and Demand

The basic equation of biological and economic life is one of limited supply of necessary goods and competition for those goods. Just as biological entities compete for limited usable energy, so too do economic entities compete for limited customer wealth and limited demand for their products. The point at which supply and demand for a given good are equal is called an equilibrium; however, in practical life, equilibrium points tend to be dynamic and changing, never static.

12. Scarcity

Game theory describes situations of conflict, limited resources, and competition. Given a certain situation and a limited amount of resources and time, what decisions are competitors likely to make, and which should they make? One important note is that traditional game theory may describe humans as more rational than they really are. Game theory is theory, after all.

13. Mr. Market

Mr. Market was introduced by the investor Benjamin Graham in his seminal book *The Intelligent Investor* to represent the vicissitudes of the financial markets. As Graham explains, the markets are a bit like a moody neighbor, sometimes waking up happy and sometimes waking up sad – your job as an investor is to take advantage of him in his bad moods and sell to him in his good moods. This attitude is contrasted to an efficient-market hypothesis in which Mr. Market always wakes up in the middle of the bed, never feeling overly strong in either direction.

The Mental Models of Military and War

1. Seeing the Front

One of the most valuable military tactics is the habit of “personally seeing the front” before making decisions – not always relying on advisors, maps, and reports, all of which can be either faulty or biased. The Map/Territory model illustrates the problem with not seeing the front, as does the incentive model. Leaders of any organization can generally benefit from seeing the front, as not only does it provide firsthand information, but it also tends to improve the quality of secondhand information.

2. Asymmetric Warfare

The asymmetry model leads to an application in warfare whereby one side seemingly “plays by different rules” than the other side due to circumstance. Generally, this model is applied by an insurgency with limited resources. Unable to out-muscle their opponents, asymmetric fighters use other tactics, as with terrorism creating fear that’s disproportionate to their actual destructive ability.

3. Two-Front War

The Second World War was a good example of a two-front war. Once Russia and Germany became enemies, Germany was forced to split its troops and send them to separate fronts, weakening their impact on either front. In practical life, opening a two-front war can often be a useful tactic, as can solving a two-front war or avoiding one, as in the example of an organization tamping down internal discord to focus on its competitors.

4. Counterinsurgency

Though asymmetric insurgent warfare can be extremely effective, over time competitors have also developed counterinsurgency strategies. Recently and famously, General David Petraeus of the United States led the development of counterinsurgency plans that involved no additional force but substantial additional gains. Tit-for-tat warfare or competition will often lead to a feedback loop that demands insurgency and counterinsurgency.

5. Mutually Assured Destruction

Somewhat paradoxically, the stronger two opponents become, the less likely they may be to destroy one another. This process of mutually assured destruction occurs not just in warfare, as with the development of global nuclear warheads, but also in business, as with the avoidance of destructive price wars between competitors. However, in a fat-tailed world, it is also possible that mutually assured destruction scenarios simply make destruction more severe in the event of a mistake (pushing destruction into the “tails” of the distribution).

The Mental Models of Human Nature and Judgment

1. Trust

Fundamentally, the modern world operates on trust. Familial trust is generally a given (otherwise we'd have a hell of a time surviving), but we also choose to trust chefs, clerks, drivers, factory workers, executives, and many others. A trusting system is one that tends to work most efficiently; the rewards of trust are extremely high.

2. Bias from Incentives

Highly responsive to incentives, humans have perhaps the most varied and hardest to understand set of incentives in the animal kingdom. This causes us to distort our thinking when it is in our own interest to do so. A wonderful example is a salesman truly believing that his product will improve the lives of its users. It's not merely convenient that he sells the product; the fact of his selling the product causes a very real bias in his own thinking.

3. Pavlovian Association

Ivan Pavlov very effectively demonstrated that animals can respond not just to direct incentives but also to associated objects; remember the famous dogs salivating at the ring of a bell. Human beings are much the same and can feel positive and negative emotion towards intangible objects, with the emotion coming from past associations rather than direct effects.

4. Tendency to Feel Envy & Jealousy

Humans have a tendency to feel envious of those receiving more than they are, and a desire "get what is theirs" in due course. The tendency towards envy is strong enough to drive otherwise irrational behavior, but is as old as humanity itself. Any system ignorant of envy effects will tend to self-immolate over time.

5. Tendency to Distort Due to Liking/Loving or Disliking/Hating

Based on past association, stereotyping, ideology, genetic influence, or direct experience, humans have a tendency to distort their thinking in favor of people or things that they like and against people or things they dislike. This tendency leads to overrating the things we like and underrating or broadly categorizing things we dislike, often missing crucial nuances in the process.

6. Denial

Anyone who has been alive long enough realizes that, as the saying goes, "denial is not just a river in Africa." This is powerfully demonstrated in situations like war or drug abuse, where denial has powerful destructive effects but allows for behavioral inertia. Denying reality can be a coping mechanism, a survival mechanism, or a purposeful tactic.

7. Availability Heuristic

One of the most useful findings of modern psychology is what Daniel Kahneman calls the Availability Bias or Heuristic: We tend to most easily recall what is salient, important, frequent, and recent. The brain has its own energy-saving and inertial tendencies that we have little control over – the availability heuristic is likely one of them. Having a truly comprehensive memory would be debilitating. Some sub-examples of the availability heuristic include the Anchoring and Sunk Cost Tendencies.

8. Representativeness Heuristic

The three major psychological findings that fall under Representativeness, also defined by Kahneman and his partner Tversky, are:

a. Failure to Account for Base Rates

An unconscious failure to look at past odds in determining current or future behavior.

b. Tendency to Stereotype

The tendency to broadly generalize and categorize rather than look for specific nuance. Like availability, this is generally a necessary trait for energy-saving in the brain.

c. Failure to See False Conjunctions

Most famously demonstrated by the Linda Test, the same two psychologists showed that students chose more vividly described individuals as more likely to fit into a predefined category than individuals with broader, more inclusive, but less vivid descriptions, even if the vivid example was a mere subset of the more inclusive set. These specific examples are seen as more representative of the category than those with the broader but vaguer descriptions, in violation of logic and probability.

9. Social Proof (Safety in Numbers)

Human beings are one of many social species, along with bees, ants, and chimps, among many more. We have a DNA-level instinct to seek safety in numbers and will look for social guidance of our behavior. This instinct creates a cohesive sense of cooperation and culture which would not otherwise be possible but also leads us to do foolish things if our group is doing them as well.

10. Narrative Instinct

Human beings have been appropriately called “the storytelling animal” because of our instinct to construct and seek meaning in narrative. It’s likely that long before we developed the ability to write or to create objects, we were telling stories and thinking in stories. Nearly all social organizations, from religious institutions to corporations to nation-states, run on constructions of the narrative instinct.

11. Curiosity Instinct

We like to call other species curious, but we are the most curious of all, an instinct which led us out of the savanna and led us to learn a great deal about the world around us, using that information to create the world in our collective minds. The curiosity instinct leads to unique human behavior and forms of organization like the scientific enterprise. Even before there were direct incentives to innovate, humans innovated out of curiosity.

12. Language Instinct

The psychologist Steven Pinker calls our DNA-level instinct to learn grammatically constructed language the Language Instinct. The idea that grammatical language is not a simple cultural artifact was first popularized by the linguist Noam Chomsky. As we saw with the narrative instinct, we use these instincts to create shared stories, as well as to gossip, solve problems, and fight, among other things. Grammatically ordered language theoretically carries infinite varying meaning.

13. First-Conclusion Bias

As Charlie Munger famously pointed out, the mind works a bit like a sperm and egg: the first idea gets in and then the mind shuts. Like many other tendencies, this is probably an energy-saving device. Our tendency to settle on first conclusions leads us to accept many erroneous results and cease asking questions; it can be countered with some simple and useful mental routines.

14. Tendency to Overgeneralize from Small Samples

It's important for human beings to generalize; we need not see every instance to understand the general rule, and this works to our advantage. With generalizing, however, comes a subset of errors when we forget about the Law of Large Numbers and act as if it does not exist. We take a small number of instances and create a general category, even if we have no statistically sound basis for the conclusion.

15. Relative Satisfaction/Misery Tendencies

The envy tendency is probably the most obvious manifestation of the relative satisfaction tendency, but nearly all studies of human happiness show that it is related to the state of the person relative to either their past or their peers, not absolute. These relative tendencies cause us great misery or happiness in a very wide variety of objectively different situations and make us poor predictors of our own behavior and feelings.

16. Commitment & Consistency Bias

As psychologists have frequently and famously demonstrated, humans are subject to a bias towards keeping their prior commitments and staying consistent with our prior selves when possible. This trait is necessary for social cohesion: people who often change their conclusions and habits are often distrusted. Yet our bias towards staying consistent can become, as one wag put it, a "hobgoblin of foolish minds" – when it is combined with the first-conclusion bias, we end up landing on poor answers and standing pat in the face of great evidence.

17. Hindsight Bias

Once we know the outcome, it's nearly impossible to turn back the clock mentally. Our narrative instinct leads us to reason that we knew it all along (whatever "it" is), when in fact we are often simply reasoning post-hoc with information not available to us before the event. The hindsight bias explains why it's wise to keep a journal of important decisions for an unaltered record and to re-examine our beliefs when we convince ourselves that we knew it all along.

18. Sensitivity to Fairness

Justice runs deep in our veins. In another illustration of our relative sense of well-being, we are careful arbiters of what is fair. Violations of fairness can be considered grounds for reciprocal action, or at least distrust. Yet fairness itself seems to be a moving target. What is seen as fair and just in one time and place may not be in another. Consider that slavery has been seen as perfectly natural and perfectly unnatural in alternating phases of human existence.

19. Tendency to Overestimate Consistency of Behavior (Fundamental Attribution Error)

We tend to over-ascribe the behavior of others to their innate traits rather than to situational factors, leading us to overestimate how consistent that behavior will be in the future. In such a situation, predicting behavior seems not very difficult. Of course, in practice this assumption is consistently demonstrated to be wrong, and we are consequently surprised when others do not act in accordance with the “innate” traits we’ve endowed them with.

20. Influence of Stress (Including Breaking Points)

Stress causes both mental and physiological responses and tends to amplify the other biases. Almost all human mental biases become worse in the face of stress as the body goes into a fight-or-flight response, relying purely on instinct without the emergency brake of Daniel Kahneman’s “System 2” type of reasoning. Stress causes hasty decisions, immediacy, and a fallback to habit, thus giving rise to the elite soldiers’ motto: “In the thick of battle, you will not rise to the level of your expectations, but fall to the level of your training.”

21. Survivorship Bias

A major problem with historiography – our interpretation of the past – is that history is famously written by the victors. We do not see what Nassim Taleb calls the “silent grave” – the lottery ticket holders who did not win. Thus, we over-attribute success to things done by the successful agent rather than to randomness or luck, and we often learn false lessons by exclusively studying victors without seeing all of the accompanying losers who acted in the same way but were not lucky enough to succeed.

22. Tendency to Want to Do Something (Fight/Flight, Intervention, Demonstration of Value, etc.)

We might term this Boredom Syndrome: Most humans have the tendency to need to act, even when their actions are not needed. We also tend to offer solutions even when we do not have knowledge to solve the problem.

23. Falsification / Confirmation Bias

What a man wishes, he also believes. Similarly, what we believe is what we choose to see. This is commonly referred to as the confirmation bias. It is a deeply ingrained mental habit, both energy-conserving and comfortable, to look for confirmations of long-held wisdom rather than violations. Yet the scientific process – including hypothesis generation, blind testing when needed, and objective statistical rigor – is designed to root out precisely the opposite, which is why it works so well when followed.

The modern scientific enterprise operates under the principle of falsification: A method is termed scientific if it can be stated in such a way that a certain defined result would cause it to be proved false. Pseudo-knowledge and pseudo-science operate and propagate by being unfalsifiable – as with astrology, we are unable to prove them either correct or incorrect because the conditions under which they would be shown false are never stated.

6. The Murder of Kitty Genovese and The Bystander Effect

Catherine “Kitty” Genovese, a New York City woman who was stabbed to death near her home in the Kew Gardens section of Queens, New York on March 13, 1964. Genovese was buried in a family grave at Lakeview Cemetery in New Canaan, Connecticut.

The circumstances of her murder and the supposed lack of reaction of numerous neighbors were reported by a newspaper article published two weeks later; the common portrayal of neighbors being fully aware but completely nonresponsive has later been criticized as inaccurate. Nonetheless, it prompted an investigation into the social psychological phenomenon that has become known as the bystander effect (seldom: “Genovese syndrome”) and especially diffusion of responsibility.

7. Taleb: The Risk Externalities of Too Big to Fail

Too Big to Fail” is a dilemma that has plagued economists, policy makers and the public at large. In Nassim Taleb’s latest paper (with co-author Charles S. Tapiero) he takes a look. Abstract

This paper examines the risk externalities stemming from the size of institutions. Assuming (conservatively) that a firm risk exposure is limited to its capital while its external (and random) losses are unbounded we establish a condition for a firm to be too big to fail. In particular, expected risk externalities’ losses conditions for positive first and second derivatives with respect to the firm capital are derived. Examples and analytical results are obtained based on firms’ random effects on their external losses (their risk externalities) and policy implications are drawn that assess both the effects of “too big to fail firms” and their regulation.

The **conclusion** is worth reading even if you don’t read the paper — a small tease. However, the non-transparent bonuses that CEOs of large banks apply to themselves while not a factor in banks failure is a violation of the trust signaled by the incentives that banks have created to maintain the payments they distribute to themselves. For these reasons, too big too fail banks may entail too large too bear risk externalities. The result we have obtained indicate that this is a fact when banks internal risks have an extreme probability distribution (as this is often the case in VaR studies) and when external risks are an unbounded Pareto distribution.

8. Gresham's Law: Why Bad Drives Out Good As Time Passes

Whenever coins containing precious metals have been used along with base metal coins of the same denomination, both legally accepted as tender, the bad coins have driven the good coins out of circulation.

Gresham's Law is named after Sir Thomas Gresham (1519-1579), an English financier in the time of the Tudors.

However, the original principle had been stated at least forty years before by Nicolaus Copernicus and has been credited to Christian and Islamic scholars even before that. In some parts of the world (mostly Central and Eastern Europe), the law is still known as the Copernicus Law.

The idea may practically date back as far as the Athenian playwright Aristophanes. In his play The Frogs, Aristophanes compares the degradation of great politicians to the introduction of bad coinage.

*I'll tell you what I think about the way
This city treats her soundest men today:
By coincidence more sad than funny,
It's very like the way we treat our money.
The noble silver drachma, which of old
We were so proud of, and the one of gold
Coins that rang so true
Throughout the world have ceased to circulate.
Instead the purses of Athenian shoppers
Are full of phoney silver-plated coppers.
Just so, when men are needed by the nation,
The best have withdrawn from circulation.*

The coinage problem is mostly obsolete in the modern age, but the practical problems are as large as ever.

The outcome described by Aristophanes is common in competing human groups or organizations: When bad behavior has taken root, and that bad behavior has a "survival advantage" against good behavior, it becomes difficult, and occasionally impossible, to drive out the bad behavior; a process akin to natural selection.

In fact, one might call Gresham's Law something of a special case of natural selection itself.

Forms of human behavior survive because they have a competitive edge against other behaviors. Self-interested groups naturally tend towards what works, so bad drives out good (in a moral sense) if it causes superior practical effects. This is one large reason why forms of regulation and policing are needed in human systems, to prevent the Law from working its magic.

In an illustration of this tendency, Charlie Munger applied Gresham's Law to 1980s savings and loan banking practices in his 1984 Letter to Wesco Shareholders:

Although interest rates have subsided from the 1981-82 peak, the low and slowly changing interest rates of former years are plainly gone with the wind, as are the former government-decreed limits on interest rate competition for savings accounts and the favoritism for savings and loan associations over banks. But an agency of the U.S. Government (...) continues to insure savings accounts in the savings and loan industry, just as it did before. The result may well be bolder and bolder conduct by many savings and loan associations. A sort of Gresham's Law ("bad loan practice drives out good") may take effect for fully competitive but deposit-insured institutions, through increased copying by cautious institutions of whatever apparent-high-yield loan and investment strategies seem to allow competitors to bid away their savings accounts and yet report substantial

earnings. If so, if "bold conduct drives out conservative conduct," there eventually could be widespread insolvencies caused by bold credit extensions come to grief.

This can be common in some business fields. Take two drug salespeople – one willing to bribe doctors to make sales, and one not willing to do so. If the industry functions such that fraudulent business practices are *not punished*, and the bribery goes uncovered by the buyer's organization, then bribery obviously gains a sustainable competitive advantage over non-bribery. Clearly, the deceptive practice will take hold, as salespeople unburdened by morals are promoted and compensated better than the high-rollers. It's a clear form of Gresham's Law.

Take also sub-prime mortgage lending practices in the lead up to the 2008 financial crisis. If two banks are competing for borrowers and one lets their standards slide to zero (or less), which is likely to prevail? Even if the practice is a "long-term loser," it can still take hold in systems where short-term incentives provide encouragement to the actual decision-makers.

Canadian Prime Minister Mackenzie King once described the origins of Gresham's Law and its effects in a similar fashion, dubbing it the Law of Competing Standards.

In the reign of Queen Elizabeth, an official named Gresham observed that where different metals were in circulation as coinage and some were better than others of the same nominal value, the coins made of the inferior metal tended to drive the better out of circulation. The better coins were either hoarded or melted down and sold as bullion, were used in the fine arts, or were absorbed in the foreign exchanges. In other words, what Gresham discovered was that cheaper money tends to drive out dearer; that when people begin to discriminate between two coinages, they will invariably pay out the inferior and hoard the better, thus removing the better from circulation. This phenomenon once generally observed came to be described as a "Law," and was identified with Gresham's name, since it was Gresham who was first successful in drawing public attention to it. Amongst money-changers, Gresham's Law of the precious metals is better known than the Ten Commandments.

Something analogous to Gresham's Law will be found to obtain in the case of competing standards in Industry. Assuming there is indifference in the matter of choice between competing commodities or services, but that in the case of such commodities or services the labor standards involved vary, the inferior standard, if brought in this manner into competition with a higher standard, will drive it out, or drag the higher down to its level. This is effected by the opportunity of under-selling which comes, where in such cases human well-being is sacrificed to material ends. The superior standard, not being recognized or demanded, is unable to hold its own, and in time disappears. This Law is just as real and relentless in its operation in Industry as Gresham's Law of the precious metals is with respect to money and the mechanism of exchange. Indeed, a more accurate exposition would describe both as manifestations of one and the same law, which I propose to call the Law of Competing Standards. I see no reason why economists should not recognize the existence of such a law, and incorporate it immediately in economic science as being quite as significant as the Law of Supply and Demand, the Law of Diminishing Returns, or any other Law accorded a place in its nomenclature.

The Law of Competing Standards is doubtless a part of the general Law of Competition, under which the cheaper of two commodities gains in competition a preference over the dearer. What Gresham discovered was an important sequence of the Law of Competition as applied to coinage; namely, the disappearance, in the course of time, of the superior metals. Observance of a like sequence in the case of standards in Industry is highly desirable. As respects labor standards, I believe that recognition of the operation of the Law of Competing Standards over ever-widening areas would do more than aught else to clear up the most baffling problems with which Industry is confronted, and to point the way to a solution of many situations which hitherto have seemed incapable of solution.

Perhaps the most important application of Gresham's Law is to avoid becoming part of systems where good behavior cannot win. Certain industries and activities lack the "policing" necessary to keep systems free from bad behavior. While it's admirable to be the "cleanest shirt" in a pile of dirty laundry, certain areas of human life do not allow the clean shirts to win.

On the flip side, you'll occasionally find situations where the good money drives out bad, and the cleanest shirts end up being worn the *most*. Those are the areas to aim your focus.

9. Lessons of the Past

The tendency to relate contemporary events to earlier events as a guide to understanding is a powerful one. The difficulty, of course, is in being certain that two situations are truly comparable. Because they are similar in some respects does not assure us that they are similar in all respects.

When we try to understand contemporary events, we often relate them to ones from the past. We do this within the context of our own lives and within the context of human history as a whole. We try to learn from our own mistakes and those of our ancestors.

The issue is that it can be hard to be sure if what is happening now and what happened before are truly comparable. They may be similar in some respects, but we cannot know if they are similar in every meaningful way.

The way we set policy is often flawed. The underrated historian Ernest May argues that we attempt to avoid the mistakes of previous generations by pursuing policies that would have made sense in the past but do not today. May wrote that lawmakers make analogies with history. However, they tend to seize upon the first which comes to mind, without considering differences. They reject disconfirming evidence. In his book, Lessons From the Past, he traces the impact of historical analogy on US foreign policy.

He found that because of reasoning by analogy, US policymakers tend to be one generation behind, determined to avoid the mistakes of the previous generation. They pursue the policies that would have been most appropriate in the historical situation but are not necessarily well adapted to the current one.

Policymakers in the 1930s, for instance, viewed the international situation as analogous to that before World War I. Consequently, they followed a policy of isolation that would have been appropriate for preventing American involvement in the first World War but failed to prevent the second. Communist aggression after World War II was seen as analogous to Nazi aggression, leading to a policy of containment that could have prevented World War II.

The Vietnam analogy had been used repeatedly over many years to argue against an activist US foreign policy. For example, some used the Vietnam analogy to argue against US participation in the Gulf War—a flawed analogy because the operating terrain over which battles were fought was completely different in Kuwait/Iraq and much more in our favor there as compared with Vietnam.

May argues that policymakers often perceive problems in terms of analogies with the past, but that they ordinarily use history badly: When resorting to an analogy, they tend to seize upon the first that comes to mind. They do not research more widely. Nor do they pause to analyze the case, test its fitness, or even ask in what ways it might be misleading.

10. Can one person successfully play different roles that require different, and often competing, perspectives?

No, according to research by Max Bazerman, author of the best book on decision making I've ever read: *Judgment in Managerial Decision Making*.

Contrary to F. Scott Fitzgerald's famous quote, "the test of a first-rate intelligence is the ability to hold two opposed ideas in the mind at the same time, and still retain the ability to function," evidence suggests that even the most intelligent find it difficult to sustain opposing beliefs without the two influencing each other.

Why?

One reason is a bias from incentives. Another is bounded awareness. The auditor who desperately wants to retain a client's business may have trouble adopting the perspective of a dispassionate referee when it comes time to prepare a formal evaluation of the client's accounting practices.

* * * * *

In many situations, professionals are called upon to play dual roles that require different perspectives. For example, attorneys embroiled in pretrial negotiations may exaggerate their chances of winning in court to extract concessions from the other side. But when it comes time to advise the client on whether to accept a settlement offer, the client needs objective advice.

Professors, likewise, have to evaluate the performance of graduate students and provide them with both encouragement and criticism. But public criticism is less helpful when faculty serve as their students' advocates in the job market. And, although auditors have a legal responsibility to judge the accuracy of their clients' financial accounting, the way to win a client's business is not by stressing one's legal obligation to independence, but by emphasizing the helpfulness and accommodation one can provide.

Are these dual roles psychologically feasible?; that is, can one person successfully play different roles that require different, and often competing, perspectives? No.

Abstract

This paper explores the psychology of conflict of interest by investigating how conflicting interests affect both public statements and private judgments. The results suggest that judgments are easily influenced by affiliation with interested partisans, and that this influence extends to judgments made with clear incentives for objectivity. The consistency we observe between public and private judgments indicates that participants believed their biased assessments. Our results suggest that the psychology of conflict of interest is at odds with the way economists and policy makers routinely think about the problem. We conclude by exploring implications of this finding for professional conduct and public policy.

11. Youngme Moon: On Business Competition and Escaping the Competitive Herd

There are many ways companies compete with one another. Unfortunately, a lot of those ways seem like nothing more than an expensive route to commoditization.

Companies are relentless in their pursuit of finding their weaknesses. They hire consultants, create branding maps, and solicit customer feedback. In our hyper-competitive world, this feedback tells us what we're missing—our weaknesses.

Companies, like people, fall into the habit of thinking the way to be better is to become more like everyone else.

- Jane's company just introduced a new line of green worms? We need green worms too preferably caffeine enhanced green worms.
- Bob decided to offer a new service? We need a new service too!
- When you ask your customers what they want they respond with what you're missing.
- When consultants compare your products to others they tell you what the competition offers that you don't.

"A funny thing happens when you begin to capture competitive differences on paper", says Harvard Professor Youngme Moon in her book Different: Escaping the Competitive Herd, "there is a natural inclination for folks in the competitive set to focus on eliminating differences rather than accentuating them."

Eliminating Differences

Our brains have been wired since birth to eliminate our differences.

We've all received school report cards. If you're like most people, at some point or another, you discovered you were below the class average in something. We all knew our parents would pick up on that weakness right away.

I cringed before coming home if I was even a hair below average in anything. After a mother saw that report card, it didn't matter how awesome you were in physics and math. The only thing that mattered was the fact that you were below average in art.

If your mother was like my mother, you wouldn't hear the end of it until you were once again average in art.

As adults, the only thing that has changed is who gives the report card.

Managers across the country hand out performance reviews that highlight your strengths and weaknesses. Of course, your boss wants you to address those weaknesses. He wants you to be more like everyone else. And since keeping your job is a pretty big incentive, you eagerly put your head down and do what you've done your whole life: rather than accentuate the differences you address your weaknesses and, in the process, become more average and indistinguishable from everyone else.

In the process, you move increasingly towards becoming a commodity.

Competition

It's like we're back in school all over; competitors and customers are telling us what we don't have—where we're below average. Only now this isn't grade school. The stakes are higher. It's winner take all and our competitive spirits take over. Except, increasingly, there is no winner.

Consumers can't tell company Y from Company X. Shelves in grocery stores are full of products that are all essentially the same. Companies think that the way to improve their laundry detergent is simply to add a new, previously unknown, fragrance. Being more of the same is, according to Moon, making brand loyalty harder to find.

Of course, if consumers pay close attention, these products have minute differences. But most of these differences are essentially meaningless.

Competing by eliminating our differences seems like nothing more than an expensive route to commoditization.

- When one airline introduced frequent flier miles the rest soon followed and the industry offerings were, once again, almost indistinguishable.
- When the Westin started offering the Heavenly Bed as a way to differentiate itself from the competition, almost immediately most other hotels at the same price point upgraded their mattresses too. The only problem was that room rates didn't increase to make up for the new investment. When everyone can offer essentially the same bed it becomes hard to differentiate yourself and raise prices in the process.

Ultimately, all of the advantages flow to the customers (and the mattress companies). According to Moon, "The more generous the baseline value proposition becomes within the category, the easier it becomes for consumers to become indifferent and the more expensive it becomes for businesses to compete." Investing in differentiation without the ability to increase prices or market share only reduces returns.

In the race to become more like everyone else, companies often don't think through the whole problem.

They "don't do the second step of the analysis which is to determine how much is going stay home and how much is just going to flow through to the customer," says longtime investor Charlie Munger.

I've never seen a single projection incorporating that second step in my life. And I see them all the time. Rather, they always read: This capital outlay will save you so much money that it will pay for itself in three years. So you keep buying things that will pay for themselves in three years. And after 20 years of doing it, somehow you've earned a return of only about 4% per annum.

If this sounds vaguely familiar it should. It's a variation of the prisoners' dilemma; the best choice for all companies is not the best choice for each individual company.

I'm not saying that all competition based on product augmentation (either through new sub-categories or new features) is a flawed strategy. Under the right circumstances, some of these investments can, and will, pan out. I am saying that if your business is pursuing one of these strategies as a means of differentiating yourself from competition, you need to critically think through this strategy.

12. The Colonel Blotto Game: How Underdogs Can Win

If you've ever wondered why underdogs win or how to improve your odds of winning when you're the underdog, this article on The Colonel Blotto Game is for you.

There is a rich tradition of celebrating wins by the weak—while forgetting those who lost—including the biblical Story of David vs. Goliath. It is notable, that “David shunned a traditional battle using a helmet and sword and chose instead to fight unconventionally with stones and a slingshot,” says Michael Mauboussin.

Luckily, David was around before Keynes said: “It is *better to fail conventionally* than to succeed unconventionally.” Turns out, if you're an underdog, David was onto something.

Despite the fact it is not as well known as the Prisoners' Dilemma, the Colonel Blotto Game can teach us a lot about strategic behavior and competition.

Underdogs can change the odds of winning simply by changing the basis of competition.

So what exactly is the Colonel Blotto Game and what can we learn from it?

In the Colonel Blotto game, two players concurrently allocate resources across n battlefields. The player with the greatest resources in each battlefield wins that battle and the player with the most overall wins is the victor.

An extremely simple version of this game would consist of two players, A and B, allocating 100 soldiers to three battlefields. Each player's goal is to create favorable mismatches versus his or her opponent.

According to Mauboussin, “The Colonel Blotto game is useful because by varying the game's two main parameters, giving one player more resources or changing the number of battlefields, you can gain insight into the likely winners of competitive encounters.”

To illustrate this point, Malcolm Gladwell tells the story of Vivek Ranadivé:

When Vivek Ranadivé decided to coach his daughter Anjali's basketball team, he settled on two principles. The first was that he would never raise his voice. This was National Junior Basketball—the Little League of basketball. The team was made up mostly of twelve-year-olds, and twelve-year-olds, he knew from experience, did not respond well to shouting. He would conduct business on the basketball court, he decided, the same way he conducted business at his software firm. He would speak calmly and softly, and convince the girls of the wisdom of his approach with appeals to reason and common sense.

The second principle was more important. Ranadivé was puzzled by the way Americans played basketball. He is from Mumbai. He grew up with cricket and soccer. He would never forget the first time he saw a basketball game. He thought it was mindless. Team A would score and then immediately retreat to its own end of the court. Team B would inbound the ball and dribble it into Team A's end, where Team A was patiently waiting. Then the process would reverse itself. A basketball court was ninety-four feet long. But most of the time a team defended only about twenty-four feet of that, conceding the other seventy feet.

Occasionally, teams would play a full-court press—that is, they would contest their opponent's attempt to advance the ball up the court. But they would do it for only a few minutes at a time. It was as if there were a kind of conspiracy in the basketball world about the way the game ought to be played, and Ranadivé thought that that conspiracy had the effect of widening the gap between good teams and weak teams. Good teams, after all, had players who were tall and could dribble and shoot well; they could crisply execute their carefully prepared plays in their opponent's end. Why, then, did weak teams play in a way that made it easy for good teams to do the very things that made them so good?

Basically, the more dimensions the game has the less certain the outcome becomes and the more likely underdogs are to win.

In other words, adding battlefields increases the number of interactions (dimensions) and improves the chances of an upset. When the basketball team cited by Malcolm Gladwell above started a full court press, it increased the number of dimensions and, in the process, substituted effort for skill.

The political scientist Ivan Arreguín-Toft recently looked at every war fought in the past two hundred years between strong and weak combatants in his book How the Weak Win Wars. The Goliaths, he found, won in 71.5 percent of the cases. That is a remarkable fact. Arreguín-Toft was analyzing conflicts in which one side was at least ten times as powerful—in terms of armed might and population—as its opponent, and even in those lopsided contests, the underdog won almost a third of the time.

In the Biblical story of David and Goliath, David initially put on a coat of mail and a brass helmet and girded himself with a sword: he prepared to wage a conventional battle of swords against Goliath. But then he stopped. “I cannot walk in these, for I am unused to it,” he said (in Robert Alter’s translation), and picked up those five smooth stones.

Arreguín-Toft wondered, what happened when the underdogs likewise acknowledged their weakness and chose an unconventional strategy? He went back and re-analyzed his data. In those cases, David’s winning percentage went from 28.5 to 63.6. When underdogs choose not to play by Goliath’s rules, they win, Arreguín-Toft concluded, “even when everything we think we know about power says they shouldn’t.”

Arreguín-Toft discovered another interesting point: *over the past two centuries the weaker players have been winning at a higher and higher rate*. For instance, strong actors prevailed in 88 percent of the conflicts from 1800 to 1849, but the rate dropped very close to 50% from 1950 to 1999.

After reviewing and dismissing a number of possible explanations for these findings, Arreguín-Toft suggests that an analysis of strategic interaction best explains the results. Specifically, when the strong and weak actors go toe-to-toe (effectively, a low n), the weak actor loses roughly 80 percent of the time because “there is nothing to mediate or deflect a strong player’s power advantage.”

In contrast, when the weak actors choose to compete on a different strategic basis (effectively increasing the size of n), they lose less than 40 percent of the time “because the weak refuse to engage where the strong actor has a power advantage.” Weak actors have been winning more conflicts over the years because they see and imitate the successful strategies of other actors and have come to the realization that refusing to fight on the strong actor’s terms improves their chances of victory. This might explain what’s happening in the Gulf War.

In the Gulf War, the number of battlefields (dimensions) is high. Even though substantially outnumbered, the Taliban, have increased the odds of “winning,” by changing the base of competition, as they did previously against the superpower Russians. It also explains why the strategy employed by Ranadivé’s basketball team, while not guaranteed to win, certainly increased the odds.

Mauboussin provides another great example:

A more concrete example comes from Division I college football. Texas Tech has adopted a strategy that has allowed it to win over 70 percent of its games in recent years despite playing a highly competitive schedule. The team’s success is particularly remarkable since few of the players were highly recruited or considered “first-rate material” by the professional scouts. Based on personnel alone, the team was weaker than many of its opponents.

Knowing that employing a traditional game plan would put his weaker team at a marked disadvantage, the coach offset the talent gap by introducing more complexity into the team’s offense via a large number of formations. These formations change the geometry of the game, forcing opponents to change their defensive strategies. It also creates new matchups (i.e., increasing n , the number of battlefields) that the stronger teams have

difficulty winning. For example, defensive linemen have to drop back to cover receivers. The team's coach explained that "defensive linemen really aren't much good at covering receivers. They aren't built to run around that much. And when they do, you have a bunch of people on the other team doing things they don't have much experience doing." This approach is considered unusual in the generally conservative game of college football. While it's easy to recall all the examples of underdogs who found winning strategies by increasing the number of competition dimensions, it's not easy to recall all of those who, employing similar dimension enhancing strategies, have failed. Another interesting point is why teams who are likely to lose use conventional strategies, which only increase the odds of failure?

According to Mauboussin:

What the analysis also reveals, however, is that nearly 80 percent of the losers in asymmetric conflicts never switch strategies. Part of the reason players don't switch is that there is a cost: when personnel training and equipment are geared toward one strategy, it's often costly to shift to another. New strategies are also stymied by leaders or organizational traditions. This type of inertia appears to be a consequential impediment to organizations embracing the strategic actions implied by the Colonel Blotto game.

Teams have an incentive to maintain a conventional strategy, even when it increases their odds of losing. Malcolm Gladwell explores:

The consistent failure of underdogs in professional sports to even try something new suggests, to me, that there is something fundamentally wrong with the incentive structure of the leagues. I think, for example, that the idea of ranking draft picks in reverse order of finish — as much as it sounds "fair" — does untold damage to the game. You simply cannot have a system that rewards anyone, ever, for losing. Economists worry about this all the time, when they talk about "moral hazard." Moral hazard is the idea that if you insure someone against risk, you will make risky behavior more likely. So if you always bail out the banks when they take absurd risks and do stupid things, they are going to keep on taking absurd risks and doing stupid things. Bailouts create moral hazard. Moral hazard is also why your health insurance has a co-pay. If your insurer paid for everything, the theory goes, it would encourage you to go to the doctor when you really don't need to. No economist in his right mind would ever endorse the football and basketball drafts the way they are structured now. They are a moral hazard in spades. If you give me a lottery pick for being an atrocious GM, where's my incentive not to be an atrocious GM?

Key takeaways:

- Underdogs improve their chances of winning by changing the basis for competition and, if possible, creating more dimensions.
- We often fail to switch strategies because of a combination of biases, including social proof, status quo, commitment and consistency, and confirmation.

13. Giffen Goods: Raising prices and increasing consumption

Other things being equal when the price of a good rises, the quantity demanded should fall. Economics refer to this as the law of demand. Because there are many counter-examples to this law it's more of a quick rule of thumb.

Giffen goods are ones which people consume more of as the price rises, thus violating the law of demand. The name comes from Sir Robert Giffen, who first proposed this paradox from his observations of the purchasing habits of the Victorian era poor.

Alfred Marshall, explains it like this:

a rise in the price of bread makes so large a drain on the resources of the poorer labouring families and raises so much the marginal utility of money to them, that they are forced to curtail their consumption of meat and the more expensive farinaceous foods: and, bread being still the cheapest food which they can get and will take, they consume more, and not less of it.

But this exceptions to the "law of demand" can be more broader than food or even inferior goods. Often a price can act as a quality indicator. More mischevious people could raise prices and use part of the profits to bribe the purchasing agent (like Visa). Amazon does this. Brian Zen does this. Mutual Funds do this. Bribing the purchasing agent is actually fairly common once you open your mind to it.

In his speech "Academic Economics Strengths and Faults after Considering Interdisciplinary needs," Charlie Munger explained:

One of the most extreme examples is in the investment management field. Suppose you're the manager of a mutual fund, and you want to sell more. People commonly come to the following answer: You raise the commissions, which of course reduces the number of units of real investments delivered to the ultimate buyer, so you're increasing the price per unit of real investment that you're selling the ultimate customer. And you're using that extra commission to bribe the customer's purchasing agent. You're bribing the broker to betray his client and put the client's money into the high-commission product. This has worked to produce at least a trillion dollars of mutual fund sales.

* * *

A real world example of what Munger was talking about:

Sanjay Bakshi offers a great real-world example of how Brian Zen, from Zenway bribes the purchasing agent.

(Brian) wants me to recommend to you, as my student, his online investment course which has helped "people with limited means to become millionaires and multi-millionaires."

Dr. Zen will charge you \$800 to sign up. He promises to pay me \$400, if you do.

You will, I hope, recall the connection between Dr. Zen's offer and Mr. Charlie Munger's example of "bribing the purchasing agent"...How, then, does one go about selling a high-priced product derived out of something so cheap? That's simple. One uses, the reward super-response tendency and the associated incentive-caused bias (whose bread I eat, his song I sing) which it produces— Mr. Munger's terms – by pricing the product high and offering a very significant part of the sales proceeds to people like me having access to "captive audience" like you.

There is nothing illegal about Dr. Zen designing his business model in this manner. After all, seeking profits is the essence of capitalism, isn't it? But I doubt it very much – if the fathers of value investing – Mr. Graham and Mr. Buffett – would approve of the marketing strategies used by Dr. Zen, for promoting products created out of their knowledge, which they generously shared with the world, without any profit motive involved.

When Wal-Mart pushes its suppliers to lower their prices, and then passes on these low prices to its customers, and yet is able to earn a respectable return on capital, it's an example of a positive-sum game which benefits civilization as a whole. Wal-Mart does not make money off its customers – it makes money with them. But when someone pushes a

high-priced product using as ammunition, mouth-watering commissions offered to people who are in a position to influence others, it largely becomes, at least in my view, a zero-sum game. You're not making money with your clients anymore- you're making money off them. And, this aspect of capitalism is not very good for civilization.

14. Predicting the Improbable

One natural human bias is that we tend to draw strong conclusions based on few observations. This bias, misconceptions of chance, shows itself in many ways including the gambler and hot hand fallacies. Such biases may induce public opinion and the media to call for dramatic swings in policies or regulation in response to highly improbable events. These biases are made even worse by our natural tendency to “do something.”

An event like an earthquake happens, making it more available in our mind.

We think the event is more probable than evidence would support so we run out and buy earthquake insurance. Over many years as the earthquake fades from our mind (making it less available) we believe, paradoxically, that the risk is lower (based on recent evidence) so we cancel our policy. ...

Some events are hard to predict. This becomes even more complicated when you consider not only predicting the event but the timing of the event as well. This article below points out that experts, like the rest of us, base their predictions on inference from observing the past and are just as prone to biases as the rest of us.

Why do people over infer from recent events?

There are two plausible but apparently contradicting intuitions about how people over-infer from observing recent events.

The gambler's fallacy claims that people expect rapid reversion to the mean.

For example, upon observing three outcomes of red in roulette, gamblers tend to think that black is now due and tend to bet more on black (Croson and Sundali 2005).

The hot hand fallacy claims that upon observing an unusual streak of events, people tend to predict that the streak will continue. (See Misconceptions of Chance)

The hot hand fallacy term originates from basketball where players who scored several times in a row are believed to have a “hot hand”, i.e. are more likely to score at their next attempt.

Recent behavioural theory has proposed a foundation to reconcile the apparent contradiction between the two types of over-inference. The intuition behind the theory can be explained with reference to the example of roulette play.

A person believing in the law of small numbers thinks that small samples should look like the parent distribution, i.e. that the sample should be representative of the parent distribution. Thus, the person believes that out of, say 6, spins 3 should be red and 3 should be black (ignoring green). If observed outcomes in the small sample differ from the 50:50 ratio, immediate reversal is expected. Thus, somebody observing 2 times red in 6 consecutive spins believes that black is “due” on the 3rd spin to restore the 50:50 ratio.

Now suppose such person is uncertain about the fairness of the roulette wheel. Upon observing an improbable event (6 times red in 6 spins, say), the person starts to doubt about the fairness of the roulette wheel because a long streak does not correspond to what he believes a random sequence should look like. The person then revises his model of the data generating process and starts to believe the event on streak is more likely. The upshot of the theory is that the same person may at first (when the streak is short) believe in reversion of the trend (the gambler's fallacy) and later – when the streak is long – in continuation of the trend (the hot hand fallacy).

15. Suppressing Volatility: Making the World Less Predictable and More Dangerous

Nassim Taleb's article, The Black Swan of Cario, ([PDF](#)) on suppressing volatility is worth a read.

It's the ultimate example of iatrogenics by the fragilista.

Here are my notes.

- Complex systems that have artificially suppressed volatility tend to become extremely fragile, while at the same time exhibiting not visible risks.
- Seeking to restrict variability seems to be good policy (who does not prefer stability to chaos?), so it is with very good intentions that policymakers unwittingly increase the risk of major blowups.
- Because policymakers believed it was better to do something than to do nothing, they felt obligated to heal the economy rather than wait and see if it healed on its own.
- Those who seek to prevent volatility on the grounds that any and all bumps in the road must be avoided paradoxically increase the probability that a tail risk will cause a major explosion. Consider as a thought experiment a man placed in artificially sterilized environment for a decade and then invited to take a ride on a crowded subway; he would be expected to die quickly.
- But although these controls might work in some rare situations, in the long-term effect of any such system is an eventual and extremely costly blowup whose cleanup costs can far exceed the benefits accrued.
- ... Government interventions are laden with unintended—and unforeseen—consequences, particularly in complex systems, so humans must work with nature by tolerating systems that absorb human imperfections rather than seek to change them.
- Although it is morally satisfying, the film (inside job) naively overlooks the fact that humans have always been dishonest and regulators have always been behind the curve.
- Humans must try to resist the illusion of control: just as foreign policy should be intelligence-proof (it should minimize its reliance on the competence of information-gathering organizations and the predictions of “experts” in what are inherently unpredictable domains), the economy should be regulator-proof, given that some regulations simply make the system itself more fragile.
- The “turkey problem” occurs when a naive analysis of stability is derived from the absence of past variations.
- Imagine someone who keep adding sand to a sand pile without any visible consequence, until suddenly the entire pile crumbles. It would be foolish to blame the collapse on the last grain of sand rather than the structure of the pile, but that is what people do consistently, and that is the policy error.
- As with a crumbling sand pile, it would be foolish to attribute the collapse of a fragile bridge to the last truck that crossed it, and even more foolish to try to predict in advance which truck might bring it down.
- Obama's mistake illustrates the illusion of local causal chains—that is, confusing catalysts for causes and assuming that one can know which catalyst will produce which effect.
- Governments are wasting billions of dollars on attempting to predict events that are produced by interdependent systems and are therefore not statistically understandable at the individual level.

- Most explanations being offered for the current turmoil in the Middle East follow the “catalysts as causes” confusion. The riots in Tunisia and Egypt were initially attributed to rising commodity prices, not to stifling and unpopular dictatorships.
- Again, the focus is wrong even if the logic is comforting. It is the system and its fragility, not events, that must be studied—what physicists call “percolation theory,” in which the properties of the terrain are studied rather than those of a single element of the terrain.
- Humans fear randomness—a healthy ancestral trait inherited from a different environment. Whereas in the past, which was a more linear world, this trait enhanced, fitness and increased changes of survival, it can have the reverse effect in today’s complex world, making volatility take the shape of nasty Black Swans hiding behind deceptive periods of “great moderation.”
- But alongside the “catalysts as causes” confusion sit two mental biases: the illusion of control and the action bias (the illusion that doing something is always better than doing nothing.) This leads to the desire to impose man-made solutions. Greenspan’s actions were harmful, but it would have been hard to justify inaction in a democracy where the incentive is to always promise a better outcome than the other guy, regardless of the actual delayed cost.
- As Seneca wrote in De clementia, “repeated punishment, while it crushes the hatred of a few, stirs the hatred of all ... just as trees that have been trimmed throw out again countless branches.”
- The Romans were wise enough to know that only a free man under Roman law could be trusted to engage in a contract; by extension, only a free people can be trusted to abide by a treaty.
- As Jean-Jacques Rousseau put it, “A little bit of agitation gives motivation to the soul, and what really makes the species prosper is not peace so much as freedom.” With freedom comes some unpredictable fluctuation. This is one of life’s packages: there is no freedom without noise—and no stability without volatility.

16. Reductionism: Understanding the Parts, Misunderstanding the Whole

In 1637 René Descartes changed the course of science forever with the publication of Discourse on the Method of Rightly Conducting One's Reason and of Seeking Truth in the Sciences. That work lays the foundation to modern science by putting forth two enduring ideas about reductionism:

1. As a way of knowing ("divide each of the difficulties under examination into as many parts as possible, and as might be necessary for its adequate solution") and;
2. To "conduct my thoughts in such order that, beginning with those objects that are simplest and most readily understood, I might ascend little by little, and, as it were, step by step, to the knowledge of the more complex."

In the article below, Robert Dorit argues the days of blind faith in the power of reductionist deconstruction are over and a new approach is taking shape. This new, interactionist perspective on living systems, emphasis on the interplay between parts (along with advances in technology to allow for modeling).

Dorit offers, "Whole new subfields in the life sciences, as well as productive interactions among existing disciplines, have emerged. Systems biologists, complexity theorists and newly minted biologists now attend as carefully to the ways in which parts come together as they do to the parts themselves." He goes on to say we are beginning to understand that modularity and redundancy are inherent features of all levels of biological organization (something Nassim Taleb has long argued). These features, he argues, are both simultaneously resilient and capable of evolving.

The "Humpty-Dumpty Problem" is one whereby we trick ourselves into believing that we understand a whole through the dissection, disassembly, and deconstruction of its parts. In doing this, we remove each individual piece from context and ignore the relationships it has with other pieces to which it is intricately connected. This is not to say that we have absolutely no understanding of a complete entity. However, to claim *full* understanding of something by breaking it into fragments and trying to put it back together again would be fallacious.

The core of Dorit's argument is not with reductionism itself but rather with the notion that *it represents the only viable strategy for understanding the living world.*

If anything, living systems consistently violate all of the criteria for reducibility. The number of elements that compose any living system—an ecosystem, an organism, an organ or a cell—is enormous. In living systems, the specific identities of these component parts matter. Unlike chemistry, for instance, in which an electron in a lithium atom is identical to an electron in a gold atom, all proteins in a cell are not equivalent or interchangeable. Each protein is the result of its own evolutionary trajectory. We understand and exploit their similarities, but their differences matter to us just as much. Perhaps most importantly, the relations between the components of living systems are complex, context-dependent and weak. In mechanical machines, the conversation taking place between the parts involves clear and unambiguous interactions. These interactions result in simple causes and effects: They are instructions barked down a simple chain of command.

Think of an escalator. Its mechanical parts and the mechanisms that are composed of those parts work together toward a collective goal. That is, to ensure that the escalator is in a constant state of upward or downward movement to transport people from point A to point B. Unlike living organisms in all their glorious complexity, there's no room for deviation or multiple outcomes in an escalator (not counting defects and malfunctions).

Dorit goes on to contrast machines with living, breathing things:

In living systems, by contrast, virtually every interesting bit of biological machinery is embedded in a very large web of weak interactions. And this network of interactions gives rise to a discussion among the parts that is less like a chain of command and more like a

complex court intrigue: ambiguous whispers against a noisy and distracting background. As a result, the same interaction between a regulatory protein and a segment of DNA can lead to different (and sometimes opposite) outcomes depending on which other proteins are present in the vicinity. The firing of a neuron can act to amplify the signal coming from other neurons or act instead to suppress it, based solely on the network in which the neuron is embedded. The disappearance of a single species can stabilize an ecosystem or send it spinning into chaos, depending on (you guessed it) the network of interactions that surrounds that species. This extensive and subtle connectivity, which gives meaning to the behavior of the underlying components, turns out to be a consistent feature of living systems.

...

The promise of reductionism rested on the belief that an intelligent dissection of complex phenomena would not only yield progress, but would eventually reduce any problem to its component parts. Complexity, we naively hoped, was simply a by-product of incomplete understanding, an illusion that would fall away once the parts were fully understood. But this is the dirty little secret of contemporary biology: Despite our reductionist successes, the central conceptual problems of biology have not yielded to study.

He clarifies this idea by providing examples where, despite the fact that the human race is in a perpetual state of exploring the uncharted and demystifying unknowns, our understanding of overarching themes that hold individual parts together falls short:

We have revealed the elegant workings of neurons in exquisite detail, but the material understanding of consciousness remains elusive. We have sequenced human genomes in their entirety, but the process that leads from a genome to an organism is still poorly understood. We have captured the intricacies of photosynthesis, and yet the consequences of rising carbon-dioxide levels for the future of the rainforests remain frustratingly hazy. We are, in short, the king's horses and the king's men: We stare at the pieces, knowing what Humpty should look like, but unable to put him together again.

17. An Introduction to the Mental Model of Redundancy (with examples)

"The reliability that matters is not the simple reliability of one component of a system, but the final reliability of the total control system."

— Garrett Hardin

We learn from Engineering that critical systems often require back up systems to guarantee a certain level of performance and minimize downtime. These systems are resilient to adverse conditions and if one fails there is spare capacity or a backup system. A simple example where you want to factor in a large margin of safety is a bridge. David Dodd, a longtime colleague of Benjamin Graham, observed *"You build a bridge that 30,000-pound trucks can go across and then you drive 10,000-pound trucks across it. That is the way I like to go across bridges."*

Looking at failure, we can see many insights into redundancy.

There are many cases of failures where the presence of redundant systems would have averted catastrophe. On the other hand, there are cases of failure where the presence of redundancy caused failure.

How can redundancy cause failure?

First, in certain cases, the added benefits of redundancy are outweighed by the risks of added complexity. Since adding redundancy increases the complexity of a system, efforts to increase reliability and safety through redundant systems may backfire and inadvertently make systems more susceptible to failure. An example of how adding complexity to a system can increase the odds of failure can be found in the near-meltdown of the Femi reactor in 1996. This incident was caused by an emergency safety device which broke off and blocked a pipe stopping the flow of coolants into the reactor core. Luckily this was before the plant was active.

Second, redundancy with people can lead to social diffusion where people always assume it was someone else who had the responsibility.

Third, redundancy can lead to increasingly risky behavior.

* * *

In Reliability Engineering for Electronic Design, Norman Fuqua gives a great introduction to the concept of redundancy.

Websters defines redundancy as needless repetition. In reliability engineering, however, redundancy is defined as the existence of more than one means for accomplishing a given task. Thus all of these means must fail before there is a system failure.

Under certain circumstance during system design, it may become necessary to consider the use of redundancy to reduce the probability of system failure—to enhance systems reliability—by providing more than one functional path or operating element in areas that are critically important to system success. The use of redundancy is not a panacea to solve all reliability problems, nor is it a substitute for good initial design. By its very nature, redundancy implies increased complexity, increased weight and space, increased power consumption, and usually a more complicated system ...

In Seeking Wisdom, Peter Bevelin mentioned some interesting quotes from Buffett and Munger that speak to the concept of redundancy/resilience from the perspective of business:

Charlie Munger

Of course you prefer a business that will prosper even if it is not managed well. We are not looking for mismanagement; we like the capacity to withstand it if we stumble into it.... We try and operate so that it wouldn't be too awful for us if something really extreme happened – like interest rates at 1% or interest rates at 20%... We try to arrange [our affairs] so that no matter what happens, we'll never have to "go back to go."

Warren Buffett uses the concept of margin of safety for investing and insurance:
We insist on a margin of safety in our purchase price. If we calculate the value of a common stock to be only slightly higher than its price, we're not interested in buying. We believe this margin-of-safety principle, so strongly emphasized by Ben Graham, to be the cornerstone of investment success.

David Dodd, on the same topic, writes:

You don't try to buy something for \$80 million that you think is worth \$83,400,000.

Buffett on Insurance:

If we can't tolerate a possible consequence, remote though it may be, we steer clear of planting its seeds.

The pitfalls of this business mandate an operating principle that too often is ignored: Though certain long-tail lines may prove profitable at combined ratios of 110 or 115, insurers will invariably find it unprofitable to price using those ratios as targets. Instead, prices must provide a healthy margin of safety against the societal trends that are forever springing expensive surprises on the insurance industry.

Confucius comments:

The superior man, when resting in safety, does not forget that danger may come. When in a state of security he does not forget the possibility of ruin. When all is orderly, he does not forget that disorder may come. Thus his person is not endangered, and his States and all their clans are preserved.

Warren Buffett talked about redundancy from a business perspective at the 2009 shareholder meeting:

Question: You've talked a lot about opportunity-costs. Can you discuss more important decisions over the past year?

Buffett: When both prices are moving and in certain cases intrinsic business value moving at a pace that's far greater than we've seen – it's tougher, more interesting and more challenging and can be more profitable. But, it's a different task than when things were moving at more leisurely pace. We faced that problem in September and October. We want to always keep a lot of money around. We have so many extra levels of safety we follow at Berkshire.

We got a call on Goldman on a Wednesday – that couldn't have been done the previous Wednesday or the next Wednesday. We were faced with opportunity-cost – and we sold something that under normal circumstances we wouldn't.

Jonathan Bendor, writing in Parallel Systems: Redundancy in Government, provides an example of how redundancy can reduce the risk of failure on cars.

Suppose an automobile had dual breaking (sic) circuits: each circuit can stop the car, and the circuits operate independently so that if one malfunctions it does not impair the other. If the probability of either one failing is 1/10, the probability of both failing simultaneously is $(1/10)^2$, or 1/100. Add a third independent circuit and the probability of the catastrophic failure of no brakes at all drops to $(1/10)^3$, or 1/1,000.

Airplane Design provides an insightful example. From the code of federal regulations:

The airplane systems and associated components, considered separately and in relation to other systems, must be designed so that the occurrence of any failure condition which would prevent the continued safe flight and landing of the airplane is extremely improbable, and the occurrence of any other failure conditions which would reduce the capacity of the airplane or the ability of the crew to cope with adverse operating conditions is improbable.

* * *

Ways redundancy can fail

In The Problem of Redundancy Problem: Why More Nuclear Security Forces May Produce Less Nuclear Security, Scott Sagan writes:

The first problem with redundancy is that adding extra components can inadvertently create a catastrophic common-mode error (a fault that causes all the components to fail). In complex systems, independence in theory (or in design) is not necessarily independence in fact. As long as there is some possibility of unplanned interactions between the components leading to common-mode errors, however, there will be inherent limits to the effectiveness of redundancy as a solution to reliability problems. The counterproductive effects of redundancy when extra components present even a small chance of producing a catastrophic common-mode error can be dramatic.

This danger is perhaps most easily understood through a simple example from the commercial aircraft industry. Aircraft manufacturers have to determine how many engines to use on jumbo jets. Cost is clearly an important factor entering their calculations. Yet so is safety, since each additional engine on an aircraft both increases the likelihood that the redundant engine will keep the plane in the air if all others fail in flight and increases the probability that a single engine will cause an accident, by blowing up or starting a fire that destroys all the other engines and the aircraft itself.

In (the image below) I assume that 40% of the time that each engine fails, it does so in a way (such as starting a catastrophic fire) that causes all the other engines to fail as well. Aircraft manufacturers make similar calculations in order to estimate how many engines would maximize safety. Boeing, for example, used such an analysis to determine that, given the reliability of modern jet engines, putting two engines on the Boeing 777, rather than three or more engines as exist on many other long-range aircraft, would result in lower risks of serious accidents.

In more complex systems or organizations, however, it is often difficult to know when to stop adding redundant safety devices because of the inherent problem of predicting the probabilities of exceedingly rare events.

...

The second way in which redundancy can backfire is when diffusion of responsibility leads to “social shirking.”

This common phenomenon—in which individuals or groups reduce their reliability in the belief that others will take up the slack—is rarely examined in the technical literature on safety and reliability because of a “translation problem” that exists when transferring redundancy theory from purely mechanical systems to complex organizations. In mechanical engineering, the redundant units are usually inanimate objects, unaware of each other’s existence. In organizations, however, we are usually analyzing redundant individuals, groups, or agencies, backup systems that are aware of one another.

...

The third basic way in which redundancy can be counterproductive is when the addition of extra components encourages individuals or organizations to increase production in dangerous ways. In most settings, individuals and organizations face both production pressures and pressure to be safe and secure. If improvements in safety and security, however, lead individuals to engage in inherently risky behavior—driving faster, flying higher, producing more nuclear energy, etc.—then expected increases in system reliability could be reduced or even eliminated. Research demonstrates, for example, that laws requiring “baby-proof” safety caps on aspirin bottles have led to an increase in child poisoning because parents leave the bottles outside the medicine cabinet.

* * *

Another example of people over-confident in redundant systems can be found in the Challenger Disaster:

A dramatic case in point is the January 1986 space shuttle Challenger explosion. A strong consensus about the basic technical cause of the accident emerged soon afterward with the publication of the Rogers Commission report: the unprecedented cold temperature at the Kennedy Space Center at the time of launch caused the failure of two critical O-rings

on a joint in the shuttle's solid rocket booster, producing a plume of hot propellant gases that penetrated the shuttle's external fuel tank and ignited its mixture of liquid hydrogen and oxygen. In contrast to the technical consensus, a full understanding of why NASA officials and Morton Thiokol engineers decided to launch the shuttle that day, despite the dangerously cold weather, has been elusive.

The Challenger launch decision can be understood as a set of individuals overcompensating for improvements in space shuttle safety that had been produced through the use of redundant O-rings. This overcompensation interpretation differs significantly from both the traditional arguments that "production pressures" forced officials to break safety rules and consciously accept an increased risk of an accident to permit the launch to take place and Diane Vaughan's more recent argument, which focuses instead on how complex rules and engineering culture in NASA created "the normalization of deviance" in which risky operations were accepted unless it could be proven that they were extremely unsafe. The production pressures explanation—that high-ranking officials deliberately stretched the shuttle flight safety rules because of political pressure to have a successful launch that month—was an underlying theme of the Rogers Commission report and is still a widely held view today.⁽³⁵⁾ The problem with the simple production pressure explanation is that Thiokol engineers and NASA officials were perfectly aware that the resilience of an O-ring could be reduced by cold temperature and that the potential effects of the cold weather on shuttle safety were raised and analyzed, following the existing NASA safety rules, on the night of the Challenger launch decision.

Vaughan's argument focuses on a deeper organizational pathology: "the normalization of deviance." Engineers and high-ranking officials had developed elaborate procedures for determining "acceptable risk" in all aspects of shuttle operations. These organizational procedures included detailed decision-making rules among launch officials and the development of specific criteria by which to judge what kinds of technical evidence could be used as an input to the decision. The Thiokol engineers who warned of the O-ring failure on the night before the launch lacked proper engineering data to support their views and, upon consideration of the existing evidence, key managers, therefore, unanimously voted to go ahead with the launch.

Production pressures were not the culprits, Vaughan insists. Well-meaning individuals were seeking to keep the risks of an accident to a minimum, and were just following the rules (p. 386). The problem with Vaughan's argument, however, is that she does not adequately explain why the engineers and managers followed the rules that night. Why did they not demand more time to gather data, or protest the vote in favor of a launch, or more vigorously call for a postponement until that afternoon when the weather was expected to improve?

The answer is that the Challenger accident appears to be a tragic example of overcompensation. There were two O-rings present in the critical rocket booster joint: the primary O-ring and the secondary O-ring were listed as redundant safety components because they were designed so that the secondary O-ring would seal even if the first leaked because of "burn through" by hot gasses during a shuttle launch. One of the Marshall space center officials summarized the resulting belief: "We had faith in the tests. The data said that the primary would always push into the joint and seal . . . And if we didn't have a primary seal in the worst case scenario, we had faith in the secondary" (p. 105).

This assumption was critical on the night of January 27, 1986 for all four senior Thiokol managers reversed their initial support for postponing the launch when a Marshall Space Center official reminded them of the backup secondary O-ring. "We were spending all of our time figuring out the probability of the primary seating," one of the Thiokol managers later noted: "[t]he engineers, Boisjoly and Thompson, had expressed some question about how long it would take that [primary] O-ring to move, [had] accepted that as a possibility,

not a probability, but it was possible. So, if their concern was a valid concern, what would happen? And the answer was, the secondary O-ring would seat”(p. 320). In short, the Challenger decision makers failed to consider the possibility that the cold temperature would reduce the resilience of both O-rings in the booster joint since that low probability event had not been witnessed in the numerous tests that had been conducted. That is, however, exactly what happened on the night of unprecedented cold temperatures. Like many automobile drivers, these decision makers falsely believed that redundant safety devices allowed them to operate in more dangerous conditions without increasing the risk of a catastrophe.

18. 3 Things Everyone Should Know About the Availability Heuristic

There are 3 things you should know about the availability heuristic:

1. We often misjudge the frequency and magnitude of events that have happened recently.
2. This happens, in part, because of the limitations on memory.
3. We remember things better when they come in a vivid narrative.

There are two biases emanating from the availability heuristic (a.k.a. the availability bias):
Ease of recall and retrievability.

Because of the availability bias, our perceptions of risk may be in error and we might worry about the wrong risks. This can have disastrous impacts.

Ease of recall suggests that if something is more easily recalled in memory it must occur with a higher probability.

The availability heuristic distorts our understanding of real risks.

“The attention which we lend to an experience is proportional to its vivid or interesting character; and it is a notorious fact that what interests us most vividly at the time is, other things equal, what we remember best.”

— William James

When we make decisions we tend to be swayed by what we remember. What we remember is influenced by many things including beliefs, expectations, emotions, and feelings as well as things like frequency of exposure. Media coverage (e.g., Internet, radio, television) makes a big difference. When rare events occur they become very visible to us as they receive heavy coverage by the media. This means we are more likely to recall it, especially in the immediate aftermath of the event. However, recalling an event and estimating its real probability are two different things. If you're in a car accident, for example, you are likely to rate the odds of getting into another car accident much higher than base rates would indicate.

Retrievability suggests that we are biased in assessments of frequency in part because of our memory structure limitations and our search mechanisms. It's the way we remember that matters.

The retrievability and ease of recall biases indicate that the availability bias can substantially and unconsciously influence our judgment. We too easily assume that our recollections are representative and true and discount events that are outside of our immediate memory.

In Thinking Fast and Slow, Kahneman writes:

People tend to assess the relative importance of issues by the ease with which they are retrieved from memory—and this is largely determined by the extent of coverage in the media.

Nobel Prize winning Social Scientist and Father of Artificial Intelligence, Herbert Simon, wrote in Models of My life:

I soon learned that one wins awards mainly for winning awards: an example of what Bob Merton calls the Matthew Effect. It is akin also to the phenomenon known in politics as “availability,” or name recognition. Once one becomes sufficiently well known, one's name surfaces automatically as soon as an award committee assembles.

* * *

According to Harvard professor Max Bazerman

Many life decisions are affected by the vividness of information. Although most people recognize that AIDS is a devastating disease, many individuals ignore clear data about how to avoid contracting AIDS. In the fall of 1991, however, sexual behavior in Dallas was

dramatically affected by one vivid piece of data that may or may not have been true. In a chilling interview, a Dallas woman calling herself C.J. claimed she had AIDS and was trying to spread the disease out of revenge against the man who had infected her. After this vivid interview made the local news, attendance at Dallas AIDS seminary increased dramatically. Although C.J.'s possible actions were a legitimate cause for concern, it is clear that most of the health risks related to AIDS are not a result of one woman's actions. There are many more important reasons to be concerned about AIDS. However, C.J.'s vivid report had a more substantial effect on many people's behavior than the mountains of data available. The Availability Heuristic describes the inferences we make about even commonness based on the ease with which we can remember instances of that event... While this example of vividness may seem fairly benign, it is not difficult to see how the availability bias could lead managers to make potentially destructive workplace decisions. The following came from the experience of one of our MBA students: As a purchasing agent, he had to select one of several possible suppliers. He chose the firm with whose name was the most familiar to him. He later found out that the salience of the name resulted from recent adverse publicity concerning the firm's extortion of funds from client companies!

Managers conducting performance appraisals often fall victim to the availability heuristic. Working from memory, vivid instances of an employee's behavior (either positive or negative) will be most easily recalled from memory, will appear more numerous than commonplace incidents, and will therefore be weighted more heavily in the performance appraisals. The recency of events is also a factor: Managers give more weight to performance during the three months prior to the evaluation than to the previous nine months of the evaluation period because it is more available in memory.

* * *

There are numerous implications for availability bias for investors.

A study by Karlsson, Loewenstein, and Ariely (2008) showed that people are more likely to purchase insurance to protect themselves after a natural disaster they have just experienced than they are to purchase insurance on this type of disaster before it happens.

Bazerman adds:

This pattern may be sensible for some types of risks. After all, the experience of surviving a hurricane may offer solid evidence that your property is more vulnerable to hurricanes than you had thought or that climate change is increasing your vulnerability to hurricanes.

Robyn M. Dawes, in his book Everyday Irrationality, says:

What is a little less obvious is that people can make judgments of the ease with which instances can come to mind without actually recalling specific instances. We know, for example, whether we can recall the presidents of the United States—or rather how well we can recall their names; moreover, we know at which periods of history we are better at recalling them than at which other periods. We can make judgments without actually listing in our minds the names of the specific presidents.

This recall of ease of creating instances is not limited to actual experience, but extends to hypothetical experience as well. For example, subjects are asked to consider how many subcommittees of two people can be formed from a committee of eight, and either the same or other subjects are asked to estimate how many subcommittees of six can be formed from a committee of eight people. It is much easier to think about pairs of people than to think about sets of six people, with the result that the estimate of pairs tends to be much higher than the estimate of subsets of six. In point of logic, however, the number of subsets of two is identical that of six; the formation of a particular subset of two people automatically involves the formation of a particular subset consisting of the remaining six. Because these unique subsets are paired together, there are the same number of each.

This availability to the imagination also creates a particularly striking irrationality, which can be termed with the conjunction fallacy or compound probability fallacy. Often combinations of events or entities are easier to think about than their components, because the combination might make sense whereas the individual component does not. A classic example is that of a hypothetical woman named Linda who is said to have been a social activist majoring in philosophy as a college undergraduate. What is the probability that at age thirty she is a bank teller? Subjects judge the probability as very unlikely. But when asked whether she might be a bank teller active in a feminist movement, subjects judge this combination to be more likely than for her to be a bank teller.

* * *

Retrievability (based on memory structures)

We are better at retrieving words from memory using the word's initial letter than a random position like 3 (Tversky & Kahneman, 1973).

In 1984 Tversky and Kahneman demonstrated the retrievability bias again when they asked participants in their study to estimate the frequency of seven-letter words that had the letter "n" in the sixth position. Their participants estimated such words to be less common than seven letter words ending in the more memorable "ing". This response is incorrect. All seven letter words ending with "ing" also have an "n" in the sixth position. However, it's easy to recall seven letter words ending with ing. As we demonstrated with Dawes above, this is another example of the conjunction fallacy.

Retail locations are chosen based on search as well, which explains why gas stations and retail stores are often "clumped" together. Consumers learn the location of a product and organize their mind accordingly. While you may not remember the name of all three gas stations on the same corner, your mind tells you that is where to go to find gas. Each station, assuming all else equal, then has a 1/3 shot at your business which is much better than gas stations you don't visit because their location doesn't resonate with your minds search. In order to maximize traffic stores must find locations that consumers associate with a product.

* * *

Exposure Effect

People tend to develop a preference for things because they are familiar with them. This is called the exposure effect. According to Titchener (1910) the exposure effect leads people to experience a "glow or warmth, a sense of ownership, a feeling of intimacy."

The exposure effect applies only to things that are perceived as neutral to positive. If you are repeatedly exposed to something perceived as a negative stimuli it may in fact amplify negative feelings. For example, when someone is playing loud music you tend to have a lot of patience at first. However, as time goes on you get increasingly aggravated as your exposure to the stimuli increases.

The more we are exposed to something the easier it is to recall in our minds. The exposure effect influences us in many ways. Think about brands, stocks, songs, companies, and even the old saying "the devil you know."

* * *

The Von Restorff Effect

"One of these things doesn't belong," can accurately summarize the Von Restorff Effect (also known as the isolation effect and novelty effect). In our minds, things that stand out are more likely to be remembered and recalled because we give increased attention to distinctive items in a set.

For example, if I asked you to remember the following sequence of characters

"RTASDT9RTGS" I suspect the most common character remembered would be the "9" because it stands out and thus your mind gives it more attention.

The Von Restorff Effect leads us to Vivid evidence.

* * *

Vivid Evidence

According to William James in the Principles of Psychology:

An impression may be so exciting emotionally as to almost leave a scar upon the cerebral tissues; and thus originates a pathological delusion. For example "A woman attacked by robbers takes all the men whom she sees, even her own son, for brigands bent on killing her. Another woman sees her child run over by a horse; no amount of reasoning, not even the sight of the living child, will persuade her that he is not killed.

M. Taine wrote:

If we compare different sensations, images, or ideas, we find that their aptitudes for revival are not equal. A large number of them are obliterated, and never reappear throughout life; for instance, I drove through Paris a day or two ago, and though I saw plainly some sixty or eighty new faces, I cannot now recall any one of them; some extraordinary circumstance, a fit of delirium, or the excitement of hashish would be necessary to give me a chance at revival. On the other hand, there are sensations with a force of revival which nothing destroys or decreases. Though, as a rule, time weakens and impairs our strongest sensations, these reappear entire and intense, without having lost a particle of their detail, or any degree of their force. M. Breirre de Boismont, having suffered when a child from a disease of the scalp, asserts that 'after fifty-five years have elapsed he can still feel his hair pulled out under the treatment of the 'skull-cap.'—For my own part, after thirty years, I remember feature for feature the appearance of the theater to which I was taken for the first time. From the third row of boxes, the body of the theater appeared to me an immense well, red and flaming, swarming with heads; below, on the right, on a narrow floor, two men and a woman entered, went out, and re-entered, made gestures, and seemed to me like lively dwarfs: to my great surprise one of these dwarfs fell on his knees, kissed the lady's hand, then hid behind a screen: the other, who was coming in, seemed angry, and raised his arm. I was then seven, I could understand nothing of what was going on; but the well of crimson velvet was so crowded, and bright, that after a quarter of an hour i was, as it were, intoxicated, and fell asleep.

Every one of us may find similar recollections in his memory, and may distinguish them in a common character. The primitive impression has been accompanied by an extraordinary degree of attention, either as being horrible or delightful, or as being new, surprising, and out of proportion to the ordinary run of life; this it is we express by saying that we have been strongly impressed; that we were absorbed, that we could not think of anything else; that our other sensations were effaced; that we were pursued all the next day by the resulting image; that it beset us, that we could not drive it away; that all distractions were feeble beside it. It is by force of this disproportion that impressions of childhood are so persistent; the mind being quite fresh, ordinary objects and events are surprising...

Whatever may be the kind of attention, voluntary or involuntary, it always acts alike; the image of an object or event is capable of revival, and of complete revival, in proportion to the degree of attention with which we have considered the object or event. We put this rule into practice at every moment in ordinary life.

An example from Freeman Dyson:

A striking example of availability bias is the fact that sharks save the lives of swimmers. Careful analysis of deaths in the ocean near San Diego shows that on average, the death of each swimmer killed by a shark saves the lives of ten others. Every time a swimmer is killed, the number of deaths by drowning goes down for a few years and then returns to the normal level. The effect occurs because reports of death by shark attack are remembered more vividly than reports of drownings.

Availability Bias is a Mental Model in the Farnam Street Mental Model Index

19. Intervention Bias: When to Step in and When To Leave Things Alone

When we want to improve a situation, our first instinct is often to change something. Try something new. Make adjustments. Anything other than what we're already doing. But this approach is frequently misguided. Sometimes doing nothing at all or removing inputs is the better approach.

Nassim Taleb, author of many books—The Black Swan, Fooled By Randomness, and The Bed of Procrustes—also wrote a book on fragility called Antifragile (antifragile defined).

One of the core ideas of Antifragile is around our tendency to intervene in situations *regardless* of whether that benefit is a net positive. There is a term for this, *iatrogenics*. Why do we do this? I can think of three good reasons: 1) we struggle to think in systems, 2) we believe that systems would benefit from our intervention and guidance, and 3) we believe that we know how to fix things to make them better.

The first reason is that we are unable to think in terms of second, third, and nth order consequences. More importantly, we are unaware that we need to. The second reason is that we see systems operating and see a flaw in the system that we could do better. Usually, it's minor. This combines with the third reason, which is we think we are the very person that needs to fix the system.

Here's Taleb expanding on this idea:

There is a mental defect psychologists call illusion of control that lead to a default to action rather than inaction, even when the benefits of inaction might be greater than those of action. So the intervention bias" (do something seems better than doing nothing, which is fine except that there are cases in which it gets us in trouble). The illusion of control was meant to show how "irrational" (according to some norm of behavior) we humans can be by giving ourselves the illusion to manage the uncontrollable around us: for instance gamblers cannot resist the pressure to do something in order to improve the outcome, such as throw the die with violence when they need a high number, or throw it softly in order to get a low one. Traders cannot resist wearing the same "lucky" shirt (often unwashed) to improve their day and feel they need to find similar way to take control of their destiny. This mental bias leads to all manner of patently "irrational" actions such as belief in paranormal, alternative medicine and many such actions often put under the umbrella magical thinking. Now the irony is that while this bias was devised to expose patently nonscientific fields, it largely affects many things you learn in college, particularly in social science. Many matters we deem scientific are just the fruit of that very illusion of control masquerading as science with, of course, actions to "improve" mankind.

Why is the scientific illusion of control worse than that of the pedestrian version? Because, tout simplement, these gamblers superstitions are benign, not much worse than doing nothing—they may be even beneficial in hidden ways, and in the right environment. But a doctor tinkering with your system or an army playing with a complex system with opaque causal links, say by invading Iraq, giving chemicals to kids and threatening their brain balance, or intervening in the environment, is far worse than nothing.

This variant of the illusion of control leads to the denigration of acts of omission (not doing something, letting things run their own course, leaving nature or the human body alone) as compared to doing something (such as operating on a patient or prescribing medication). This, we will see is the reason medicine used, until recent history, to kill more patients than it saved (and did not even get close to realizing it), and economists of the sophisticated equation-carrying variety, I will hope to convince you, have been particularly harmful to the economic health of societies—central bankers, and finance ministers, by tinkering with economic life, have caused massive instability.

20. The Tragedy Of The Commons

What is common to many is taken least care of, for all men have greater regard for what is their own than for what they possess in common with others. — Aristotle

The rules pay you to do the wrong thing. — Garrett Hardin

The Tragedy of the Commons is a parable that illustrates why common resources get used more than is desirable from the standpoint of society as a whole.

Garrett Hardin, introduces us to the The Tragedy of the Commons:

Picture a pasture open to all. It is to be expected that each herdsman will try to keep as many cattle as possible on the commons. Such an arrangement may work reasonably satisfactorily for centuries because tribal wars, poaching, and disease keep the numbers of both man and beast well below the carrying capacity of the land. Finally, however, comes the day of reckoning, that is, the day when the long-desired goal of social stability becomes a reality. At this point, the inherent logic of the commons remorselessly generates tragedy.

As a rational being, each herdsman seeks to maximize his gain. Explicitly or implicitly, more or less consciously, he asks, "What is the utility to me of adding one more animal to my herd?" This utility has one negative and one positive component.

1) The positive component is a function of the increment of one animal. Since the herdsman receives all the proceeds from the sale of the additional animal, the positive utility is nearly +1.

2) The negative component is a function of the additional overgrazing created by one more animal. Since, however, the effects of overgrazing are shared by all the herdsmen, the negative utility for any particular decision-making herdsman is only a fraction of 1.

Adding together the component partial utilities, the rational herdsman concludes that the only sensible course for him to pursue is to add another animal to his herd. And another; and another. . . . But this is the conclusion reached by each and every rational herdsman sharing a commons. Therein is the tragedy. Each man is locked into a system that compels him to increase his herd without limit—in a world that is limited. Ruin is the destination toward which all men rush, each pursuing his own best interest in a society that believes in the freedom of the commons. Freedom in a commons brings ruin to all.

Greg Mankiw, in his Microeconomics text says:

Consider life in a small medieval town. Of the many economic activities that take place in the town, one of the most important is raising sheep. Many of the town's families own flocks of sheep and support themselves by selling the sheep's wool, which is used to make clothing.

As our story begins, the sheep spend much of their time grazing on the land surrounding the town, called the Town Commons. No family owns the land. Instead the town residents own the land collectively, and all the residents are allowed to graze their sheep on it.

Collective ownership works well because land is plentiful. As long as everyone can get all the good grazing land they want, the Town Common is not a rival good and allowing residents' sheep to graze for free causes no problems. Everyone in the town is happy.

As the years pass, the population of the town grows and so does the number of sheep grazing on the Town Commons. With a growing number of sheep and a fixed amount of land, the land starts to lose its ability to replenish itself. Eventually, the land is grazed so heavily that it becomes barren. With no grass left on the Town Common, raising sheep is impossible, and the town's once prosperous wool industry disappears and, tragically, many families lose their source of livelihood.

What causes the tragedy? Why do the shepherds allow the sheep population to grow so large that it destroys the Town Common? The reason is that social and private incentives differ. Avoiding the destruction of the grazing land depends on the collective action of the shepherds. If the shepherds acted together, they could reduce the sheep population to a

size that the Town Common could support. Yet no single family has an incentive to reduce the size of its own flock because each flock represents only a small part of the problem. In essence, the Tragedy of the Commons arises because of an externality. When one family's flock grazes on the common land, it reduces the quality of the land available for other families. Because people neglect this negative externality when deciding how many sheep to own, the result is an excessive number of sheep.

If the tragedy had been foreseen, the town could have solved the problem in various ways. It could have regulated the number of sheep in each family's flock, internalized the externality by taxing sheep, or auctioned off a limited number of sheep grazing permits. That is, the medieval town could have dealt with the problem of overgrazing in the way that modern society deals with the problem of pollution.

In the case of land, however, there is a simpler solution. The town can divide up the land among town families. Each family can enclose its allotment of land with a fence and then protect it from excessive grazing. In this way, the land becomes a private good rather than a common resource. This outcome in fact occurred during the enclosure movement in England in the 17th century.

The Tragedy of the Commons is a story with a general lesson: when one person uses a common resource, he diminishes other people's enjoyment of it. Because of this negative externality, common resources tend to be used excessively. The government can solve the problem by reducing use of the common resource through regulation or taxes.

Alternatively, the government can sometimes turn the common resource into a private good.

This lesson has been known for thousands of years. The ancient Greek philosopher Aristotle pointed out the problem with common resources: 'What is common to many is taken least care of, for all men have greater regard for what is their own than for what they possess in common with others.'

21. Alignment: The Key to Success Nobody Ever Taught You

I spend a lot of time thinking about this simple idea: The person who aligns themselves with the general principles of the world goes further and faster than the person who doesn't.

What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson.

— Joseph Tussman

The way to align yourself with the world is to take simple ideas seriously.

Consider compounding.

We know that spending less than we make, investing the difference in index funds, and waiting for a long time creates financial independence. Yet how many people follow this principle? Not many. Most of us know what works but fail to align ourselves with it.

Compounding applies to relationships too. Not just with your partner, but with your colleagues, friends, and even your customers. For relationships to compound, they must be win-win. But how many people take a consistent win-win approach? Not many. Again, we know what works, but fail to align ourselves with it.

Outcome over Ego

Here's the trick to seeing things differently: put your energy into *being* right, not *feeling* right. While that sounds simple, it's far from easy.

If you want to be right, you have to change your mind. When the evidence indicates the approach isn't working, change the approach. This is easy with something like math, where the answers are black and white, but harder with more subjective things.

Often the hardest things to change our minds about are the things that require us to understand that just because we can't see the results immediately doesn't mean they are not moving us closer or further from the outcome we want. For instance, eating a full pizza once won't make you unhealthy, but repeating that choice daily for years certainly will.

Feeling right, on the other hand, often requires you to believe you are an exception. You know the path to financial independence, but that takes too long. It's boring. Instead, you'd rather try the latest incarnation of a get-rich-quicker scheme that promises the outcome sooner. When it inevitably fails to produce the desired results, rather than tell yourself you made a mistake you chalk it up to the world not working as it should. It's as if that little voice in your head says, "You're not wrong; the world is."

Most of us would rather bargain with how the world works than accept how it does work, cooperate with it, and move forward. This happens in a lot of areas of life. Consider the general concept of health.

A lot of people think they don't have to take care of their health. They get too little sleep. They drink too much. They eat incredible amounts of processed food. They get little to no exercise. While they know health is important, at some level they think they are the exception. Acceptance is knowing you must care for your health because it is the foundation for everything else. Without health, everything else multiplies by zero.

We are tempted to believe we're the exception because it's the easy path.

Aligning with the world often requires you to pre-pay now for a result later. A little bit of pain today for gain tomorrow. And we don't like the sounds of that.

However, if you can align yourself with the world despite what those around you do, you'll quickly discover that it tends to do most of the work for you. It just won't take the first step for you. You have to take that one for yourself.

22. Kantian Fairness Tendency: The World Isn't Fair

The Kantian Fairness Tendency refers to the pursuit of perfect fairness which causes a lot of terrible problems. Stop expecting the world to be fair and adjust your behavior accordingly.

To learn about this mental model we turn to Charlie Munger, who mentioned it twice.

First in this UCCB talk entitled Academic Economics — Strengths and Weaknesses, after Considering Interdisciplinary Needs where he said:

It is not always recognized that, to function best, morality should sometimes appear unfair, like most worldly outcomes. The craving for perfect fairness causes a lot of terrible problems in system function. Some systems should be made deliberately unfair to individuals because they'll be fairer on average for all of us. I frequently cite the example of having your career over, in the Navy, if your ship goes aground, even if it wasn't your fault. I say the lack of justice for the one guy that wasn't at fault is way more than made up by a greater justice for everybody when every captain of a ship always sweats blood to make sure the ship doesn't go aground. Tolerating a little unfairness to some to get a greater fairness for all is a model I recommend to all of you. But again, I wouldn't put it in your assigned college work if you want to be graded well, particularly in a modern law school wherein there is usually an over-love of fairness-seeking process.

The second time was in his essay entitled: The Psychology of Human Misjudgment:

Kant was famous for his "categorical imperative," a sort of a "golden rule" that required humans to follow those behavior patterns that, if followed by all others, would make the surrounding human system work best for everybody. And it is not too much to say that modern acculturated man displays, and expects from others, a lot of fairness as thus defined by Kant.

In a small community having a one-way bridge or tunnel for autos, it is the norm in the United States to see a lot of reciprocal courtesy, despite the absence of signs or signals. And many freeway drivers, including myself, will often let other drivers come in front of them, in lane changes or the like, because that is the courtesy they desire when roles are reversed. Moreover, there is, in modern human culture, a lot of courteous lining up by strangers so that all are served on a "firstcome-first-served" basis.

Also, strangers often voluntarily share equally in unexpected, unearned good and bad fortune. And, as an obverse consequence of such "fair-sharing" conduct, much reactive hostility occurs when fairsharing is expected yet not provided. It is interesting how the world's slavery was pretty well abolished during the last three centuries after being tolerated for a great many previous centuries during which it coexisted with the world's major religions. My guess is that Kantian Fairness Tendency was a major contributor to this result.

* * *

Professor Sanjay Bakshi makes a connection between the Kantian Fairness Tendency and the "law of the higher good" in reference to Machiavelli's famous book The Prince.

Bakshi said this to his students:

Machiavelli's "The Prince" is a great book and should be made compulsory reading for all MBA students.

To many people, The Prince is an evil book. But Joseph L. Badaracco, who teaches a hugely popular course titled "The Moral Leader" at the Harvard Business School uses this book to teach ethics. And he teaches ethics by telling students to follow Machiavelli's advice in The Prince.

In an interview, Badaracco has said that four different takes on The Prince usually emerge in classroom discussions of The Prince at HBS:

Version 1 : "This book is a mess. It was written by a guy who hoped to get to the center of things, was there briefly, offended some of the wrong Medicis, was exiled, was tortured,

and wanted to get back in.” It’s “a scholar’s dream because you can find anything you want in it and play intellectual games. But just put it aside.”

Version 2 : “Now wait a minute. There’s some good common sense in there. Machiavelli is basically saying that if you want to make an omelet you have to break some eggs... To do some right things, you may have to not do some other right things.”

Version 3 : Other students believe the book is still around because it’s so evil. Why is it evil? “If you look closely at *The Prince*,” he said, “it’s quite interesting what isn’t in the book. Nothing about religion. Nothing about the Church. Nothing about God. There’s nothing about spirituality. Almost nothing about the law. Almost nothing about traditions. You’re out there on your own doing what works for you in terms of naked ambition.”

Version 4 : “A fourth Prince that other students uncover is the most interesting one, in Badaracco’s mind. Students find that the book reveals a kind of worldview, he says, and it’s not an evil worldview. This version goes: “If you’re going to make progress in the world you’ve got to have a clear sense, a realistic sense, an unsentimental sense, of how things really work: the mixed motives that compel some people and the high motives that compel some others. And the low motives that unfortunately captivate other people.” Students who claim the fourth Prince, Badaracco said, believe that if they’re going to make a difference, it’s got to be in this world, “and not in some ideal world that you would really like to live in.”

One of my favourite mental models comes from *The Prince*. I call this model, the “law of the higher good”. Before I read *The Prince*, I read an excellent book called, “*The Contrarian Guide to Leadership*” by Steven Sample. In this book, which was recommended by Mr. Munger, Sample’s thoughts on the law of the higher good from *The Prince* resonated very well with what Mr. Munger has been advocating for years.

I reproduce here an excerpt from Sample’s book which deals with the law of the higher good:

“Let me clarify the most fundamental misunderstanding. Machiavelli was not an immoral or even an amoral man; as mentioned earlier, he had a strong set of moral principles. But he was driven by the notion of a higher good: an orderly state in which citizens can move about at will, conduct business, safeguard their families and possessions, and be free of foreign intervention or domination. Anything which could harm this higher good, Machiavelli argued, must be opposed vigorously and ruthlessly. Failure to do so out of either weakness or kindness was condemned by Machiavelli as being contrary to the interests of the state, just as it would be contrary to the interests of a patient for his surgeon to refuse to perform a needed operation out of fear that doing so would inflict pain on the patient.”

The law of the higher good is a terribly useful model for leaders because it forces them to think about things from a totally different perspective.

Here’s a hypothetical situation to ponder about:

You are in charge of running a retail store and one of your cashiers, an elderly woman, is caught committing a minor embezzlement. Fearing that she might be dismissed, she approaches you to plead forgiveness. She tells you that this is the first time she embezzled money from the company and promises that she’ll never do it again. She tells you about her sad situation, namely that her husband is very ill and that she was going to use the money to buy medicines for him. She becomes extremely emotional and your heart is melting. What do you do?

Something similar to the above situation was described by Mr. Munger in a talk given by him. He used two models to produce his answer. The first model was probability. Mr. Munger implores you to reduce the problem to the mathematics of Fermat/Pascal by asking the question: How likely is it that the old woman’s statement, “I’ve never done it before, I’ll never do it again” is true?

Note that this question has nothing whatsoever to do with the circumstances in this particular instance of embezzlement. Rather, Munger is relying on his knowledge of the

theory of probability. He asks: "If you found 10 embezzlements in a year, how many of them are likely to be first offences?"

The possible actions are: (1) She is lying and you fire her (good outcome – because it cures the problem and sends the right signals); (2) She is telling the truth and you fire her (bad outcome for her but good outcome for system integrity); (3) She is lying and you pardon her (bad outcome for system integrity); and (4) She is telling the truth and you pardon her (bad outcome for system integrity because it will send the wrong signal that its ok to embezzle once).

Weighed with probabilities, and after considering signalling effects of your actions on other people's incentives and its effect on system integrity, its clear that the woman should be fired.

Looked this way, this is not a legal problem or an ethical problem. Its an arithmetical problem with a simple solution. This extreme reductionism of practical problems to a fundamental discipline (in this case mathematics), is, of course, the hallmark of the Munger way of thinking and living.

So, from a leader's perspective, it's more important to have the right systems with the right incentives in place, rather than trying to be fair to one person – even if that person is the leader or someone close to the leader.

The logic is that leaders must look at such situations from their civilization's point of view rather than the viewpoint of an individual. If we create systems which encourage embezzlements, or tolerate such systems, we'll ruin our civilization. If we don't punish the woman, the idea that its ok to do minor embezzlement once in a while, will spread because of incentive effects, and social proof (everyone's doing it so its ok). And we cannot let that idea spread because that will ruin our civilization. Its that simple.

23. Definition of a Black Swan

A black swan is a rare unexpected event. Black swans can be positive or negative. There are ways to account for this problem including an understanding of The Lucretius Problem, factoring in a Margin of Safety, and having skin in the game.

In The Black Swan: The Impact of the Highly Improbable, Nassim Taleb offers a definition of a black swan.

Taleb writes:

an event with the following three attributes. First, it is an outlier, as it lies outside the realm of regular expectations, because nothing in the past can convincingly point to its possibility. Second, it carries an extreme impact.... Third, in spite of its outlier status, human nature makes us concoct explanations for its occurrence after the fact, making it explainable and predictable.

Black swans are the inevitable byproduct of complex adaptive systems. Think about the world as a collection of interactions between components that are generally predictable but not always.

Knowing the behaviors of the individual part can allow you to extrapolate the behavior of the group most of the time. However, it won't allow you to predict the behavior of each interaction. Occasionally these interactions will produce something unexpected and result in non-linear and non-predictable behavior.

One of the biggest mistakes that people make with black swans comes with a big impact. A lot of people think that when outcomes occur outside of *their* expectations that the result is a black swan. This reasoning causes the belief that the outcome could not have been foreseen, because *they* didn't foresee it. While this reasoning loop relaxes our brain and allows us to avoid feedback, it also ensures that we are not learning how the world really works. We become close-minded.

Just because something is outside of *our* expectations does not make it a black swan.

24. Daniel Kahneman: Some Thoughts on Thinking

While Daniel Kahneman's book, Thinking Fast, Thinking Slow, gets all the attention, he's also written a few articles that might catch your interest on thinking better.

Optimistic Bias:

In terms of its consequences for decisions, the optimistic bias may well be the most significant cognitive bias. Because optimistic bias is both a blessing and a risk, you should be both happy and wary if you are temperamentally optimistic.

Competition Neglect

Colin Camerer, who coined the concept of competition neglect, illustrated it with a quote from a chairman of Disney Studios. Asked why so many big-budget movies are released on the same holidays, he said, "Hubris. Hubris. If you only think about your own business, you think, 'I've got a good story department, I've got a good marketing department' ... and you don't think that everybody else is thinking the same way." The competition isn't part of the decision. In other words, a difficult question has been replaced by an easier one. This is a kind of dodge we all make, without even noticing. We use fast, intuitive thinking — System 1 thinking — whenever possible, and switch over to more deliberate and effortful System 2 thinking only when we truly recognize that the problem at hand isn't an easy one.

The question that studio executives needed to answer is this: Considering what others will do, how many people will see our film? The question they did consider is simpler and refers to knowledge that is most easily available to them: Do we have a good film and a good organization to market it?

Appreciation of uncertainty

As Nassim Taleb, the author of "The Black Swan," has argued, inadequate appreciation of the uncertainty of the environment inevitably leads economic agents to take risks they should avoid. However, optimism is highly valued; people and companies reward the providers of misleading information more than they reward truth tellers. An unbiased appreciation of uncertainty is a cornerstone of rationality — but it isn't what organizations want. Extreme uncertainty is paralyzing under dangerous circumstances, and the admission that one is merely guessing is especially unacceptable when the stakes are high. Acting on pretended knowledge is often the preferred approach.

Theory-induced blindness

Bernoulli invented psychophysics to explain this aversion to risk. His idea was straightforward: People's choices are based not on dollar values but on the psychological values of outcomes, their utilities. The psychological value of a gamble is therefore not the weighted average of its possible dollar outcomes; it is the average of the utilities of these outcomes, each weighted by its probability.

...That Bernoulli's theory prevailed for so long is even more remarkable when you see that, in fact, it is seriously flawed. The errors are found not in what it asserts explicitly, but what it tacitly assumes.

The mystery is how a conception that is vulnerable to such obvious counterexamples survived for so long. I can explain it only by a weakness of the scholarly mind that I have often observed in myself. I call it theory-induced blindness: Once you have accepted a theory, it is extraordinarily difficult to notice its flaws. As the psychologist Daniel Gilbert has observed, disbelieving is hard work.

Reference points and loss aversion

The economists Devin Pope and Maurice Schweitzer, at the University of Pennsylvania, suggest that golf provides the perfect example of a reference point: par. For a professional golfer, a birdie (one stroke under par) is a gain, and a bogey (one stroke over par) is a loss. Failing to make par is a loss, but missing a birdie putt is a forgone gain, not a loss.

Pope and Schweitzer analyzed more than 2.5 million putts to test their prediction that players would try harder when putting for par than when putting for a birdie.

They were right. Whether the putt was easy or hard, at every distance from the hole, players were more successful when putting for par than for a birdie.

...If you are set to look for it, the asymmetric intensity of the motives to avoid losses and to achieve gains shows up almost everywhere. It is an ever-present feature of negotiations, especially of renegotiations of an existing contract, the typical situation in labor negotiations, and in international discussions of trade or arms limitations. Loss aversion creates an asymmetry that makes agreements difficult to reach.

Negotiations over a shrinking pie are especially difficult because they require an allocation of losses. People tend to be much more easygoing when they bargain over an expanding pie.

In the world of territorial animals, the principle of loss aversion explains the success of defenders. A biologist observed that “when a territory holder is challenged by a rival, the owner almost always wins the contest — usually within a matter of seconds.”

25. Mental Model: Feedback Loops

Feedback loops are created when reactions affect themselves and can be positive or negative.

Consider a thermostat regulating room temperature. This is an example of a negative feedback loop. As the temperature rises, the thermostat turns off the furnace allowing the room to rest at a predetermined temperature. When the temperature falls below that predetermined temperature the furnace reignites to return the room to its equilibrium state. Other examples include body temperature and financial markets.

Referring to the credit problems in 2008/2009, Vice Chairman of Berkshire Hathaway, Charlie Munger explained:

By the fourth quarter, the credit crisis, coupled with tumbling home and stock prices, had produced a paralyzing fear that engulfed the country. A free-fall in business activity ensued, accelerating at a pace that I have never before witnessed. The U.S. — and much of the world — became trapped in a vicious negative-feedback cycle. Fear led to business contraction, and that in turn led to even greater fear.

* * *

In The Education of a Speculator, Victor Niederhoffer says:

One of the common features that all life possesses is a mechanism for maintaining orderly conditions. This tendency is called homeostasis. In system theory, it is called negative feedback ... A Common homeostatic behavior in humans is temperature regulation. If the temperature rises above the 98.6 F optimum for normal human activity, sensors on the skin detect it and signal the brain that a rise has occurred. The brain relays the information to the effectors that increase blood flow to the skin. This induces perspiration. The loss in heat, caused by evaporation, lowers the body temperature. When the body cools below a certain point, a comparable mechanism is set off, this time reducing blood flow and causing shivering. This activity generates heat through physical activity thus raising the body temperature.

In Universal Principles of Design, William Lidwell, Jill Butler, and Kritina Holden write:

Every action creates an equal and opposite reaction. When reactions loop back to affect themselves, a feedback loop is created. All real-world systems are composed of many such interacting feedback loops — animals, machines, businesses, and ecosystems, to name a few. There are two types of feedback loops: positive and negative. Positive feedback amplifies system output, resulting in growth or decline. Negative feedback dampers output, stabilizes the system around an equilibrium point.

Positive feedback loops are effective for creating change, but generally result in negative consequences if not moderated by negative feedback loops. For example, in response to head and neck injuries in football in the late 1950s, designers created plastic football helmets with internal padding to replace leather helmets. The helmets provided more protection, but induced players to take increasingly greater risks when tackling. More head and neck injuries occurred (after the introduction of plastic helmets) than before. By concentrating on the problem in isolation (e.g., not considering changes in player behavior) designers inadvertently created a positive feedback loop in which players used their head and neck in increasingly risky ways. This resulted in more injuries which resulted in additional redesigns that made the helmet shells harder and more padded and so on. Negative feedback loops are effective for resisting change. For example, the Segway Human Transporter uses negative feedback loops to maintain equilibrium. As a rider leans forward or backward, the Segway accelerates or decelerates to keep the system in equilibrium. To achieve this smoothly, the Segway makes hundreds of adjustments every second. Given the high adjustment rate, the oscillations around the point of equilibrium are so small as to not be detectable. However, if fewer adjustments were made per second, the oscillations would increase in size and the ride would become increasingly jerky.

A key lesson of feedback loops is that things are connected—changing one variable in a system will affect other variables in that system and other systems. This is important because it means that designers must not only consider particular elements of a design, but also their relation to the design as a whole and to the greater environment.

From Graph Algebra by Courtney Brown:

Feedback loops are typically used to accomplish regulation and control. A feedback loop is like an input, but its origin is from within the system itself, not from outside the system. In many systems, the output reenters the system as another input. This is exactly what happens with a microphone and speakers when the sound from the speakers feed back into the microphone, often causing a loud squeal.

Sanjay Bakshi, a visiting professor at MDI wrote an email to one of his students on positive feedback:

In my view, its not correct to always view positive feedback loops in business as destructive, though they well might be. For example a run on a bank can bring it down on its knees in a very short time period and it can spread (systemic risk) to other banks. Similarly stock market bubbles can be thought of positive feedback loops – high prices feed optimism which feeds high prices – it does not last for ever, but it can last for a long long time.

I think you're on the right track when you visualize a positive feedback loop as a mechanism which is nested inside a negative feedback loop. To illustrate, why do bear markets follow bull markets? Because over the long run, markets operate inside a negative feedback loop with built-in corrective mechanisms. When prices run too far away from underlying values, there are forces that pull them back. For example, when stocks become too cheap in relation to the replacement cost of the underlying assets, there is no incentive to create new capacity and industry consolidation is likely to take place wherein the strong players in an industry, instead of creating new capacity, buy out competitors. Conversely, when stock prices rise so high that they become much more than the replacement cost of the underlying assets, strong incentives are created by those high prices, to create fresh capacity. So shortages follow gluts follow shortages.... – hence a negative feedback loop.

But what caused the speculative bubble in the first place? Why do people suddenly become euphoric about an industry or a sector and invest in it in unison? That part of the answer is better explained by positive feedback loops.

Its also important to view positive feedback loops as means of explaining some of the extreme business successes. I gave two examples in class of the dominant newspaper, and Wal-Mart. But one can think of others. For example, in some industries, the first mover has a big advantage. He goes and captures a very large part of the market and obtains scale economics. And once he's done that, it becomes very difficult to dislodge him.

In 2005 Michael Mauboussin, Chief Investment Strategist at Legg Mason Capital Management offered¹:

The last idea has to do with systems that exhibit super-linear behavior vs. those that exhibit sub-linear behavior. In the super-linear systems, when you add more, you create more: there's a positive feedback loop. One of the most direct uses of this in markets is network effects—the value of a good or service increases as more people use that good or service. The prototypical example would be eBay. They started out with their basic auction business which has very clear network effects. Then they moved into PayPal which is a payment business. It also derived benefits from network effects. Last week they announced the acquisition of Skype. Once again it's a network effects business.

Sub-linear systems are concerned with maximizing efficiency per unit in industries that are relatively mature. Using capital to innovate may not be the best path for these types of companies: they should work on efficiency instead.

In 2002, Mauboussin offered an example of ants and positive feedback:

The power of this collective effect has not been lost on nature. This is where Johnson's stories about ants come in. How do the ants do it? Foraging ants depart the nest with one job in mind, to find and retrieve food. They also have the ability to leave and follow chemical trails. At first, they disperse randomly. When the ants that find food come back to the nest, they leave a chemical trail that their sisters can follow. Studies show that this process allows ants to consistently find the shortest path to the food.

Once researchers understood this collective ability, they decided to play a trick on the ants. In a controlled setting, the scientists placed two food sources at identical path lengths from the nest. As it turned out, the ants ended up using just one of the paths, although which one they chose was random. Why? Because they follow chemical trails, a couple more ants going down one path will attract other ants, triggering a positive feedback loop. So instead of finding an optimal solution, the ants have one crowded path and an equidistant, empty path. Amazingly, though, nature anticipated this problem as well. As it turns out, ants periodically break from the main path and begin a random search process again. The ants are programmed to strike a balance between exploiting a known food source and exploring for the next food source. The ants are hard-wired to seek diversity.

In Earth in the Balance, Al Gore writes:

When I was flying over the Amazon rain forest in small plane I was struck by what happened immediately after a thunderstorm moved across an area of the forest: as soon as the rain stopped, clouds of moisture began to rise from the trees to form new rain clouds that moved west, driven by the wind, where they provided the water for new rain falling out of new thunderstorms. Any interruption of this natural process can have a magnificent impact. When large areas of rain forest are burned, the amount of rainfall recycled to adjacent areas is sharply reduced, depriving those areas of the rain they need to maintain their healthy condition. If the deforested area is large enough, the amount of rainfall removed from adjacent areas will be enough to cause a reinforcing drought cycle, which slowly kills more trees, thus further reducing rainfall recycling and accelerating the death of the forest in turn.

From Thomas Goetz in Wired:

...So feedback loops work. Why? Why does putting our own data in front of us somehow compel us to act? In part, it's that feedback taps into something core to the human experience, even to our biological origins. Like any organism, humans are self-regulating creatures, with a multitude of systems working to achieve homeostasis. Evolution itself, after all, is a feedback loop, albeit one so elongated as to be imperceptible by an individual. Feedback loops are how we learn, whether we call it trial and error or course correction. In so many areas of life, we succeed when we have some sense of where we stand and some evaluation of our progress. Indeed, we tend to crave this sort of information; it's something we viscerally want to know, good or bad. As Stanford's Bandura put it, "People are proactive, aspiring organisms." Feedback taps into those aspirations.

* * *

Richard Koch:

In the absence of feedback loops, the natural distribution of phenomena would be 50/50—inputs of a given frequency would lead to commensurate results. It is only because of positive and negative feedback loops that causes do not have equal results. Yet it also seems to be true that powerful positive feedback loops only affect a small minority of the inputs.

26. Mental Model: Conjunctive and Disjunctive Events Bias

Welcome to the conjunctive and disjunctive events bias.

Why are we so optimistic in our estimation of a project's cost and schedule? Why are we so surprised when something inevitably goes wrong? Because of the human tendency to underestimate disjunctive events.

According to Daniel Kahneman and his long-time co-author Amos Tversky (1974): "A complex system, such as a nuclear reactor or the human body, will malfunction if any of its essential components fails." They continue, "Even when the likelihood of failure in each component is slight, the probability of an overall failure can be high if many components are involved."

In Seeking Wisdom: From Darwin to Munger, Peter Bevelin writes:

A project is composed of a series of steps where all must be achieved for success. Each individual step has some probability of failure. We often underestimate the large number of things that may happen in the future or all opportunities for failure that may cause a project to go wrong. Humans make mistakes, equipment fails, technologies don't work as planned, unrealistic expectations, biases including sunk cost-syndrome, inexperience, wrong incentives, changing requirements, random events, ignoring early warning signals are reasons for delays, cost overruns and mistakes. Often we focus too much on the specific base project case and ignore what normally happens in similar situations (base rate frequency of outcomes—personal and others). Why should some project be any different from the long-term record of similar ones? George Bernard Shaw said: "We learn from history that man can never learn anything from history."

The more independent steps that are involved in achieving a scenario, the more opportunities for failure and the less likely it is that the scenario will happen. We often underestimate the number of steps, people, and decisions involved.

Add to this that we often forget that the reliability of a system is a function of the whole system. The weakest link sets the upper limit for the whole chain.

* * *

In "Thinking, Fast and Slow", Kahneman offers the following example:

Linda is thirty-one years old, single, outspoken, and very bright. She majored in philosophy. As a student, she was deeply concerned with the issues of discrimination and social justice, and also participated in antinuclear demonstrations.

Which alternative is most probable:

Linda is a bank teller.

Linda is a bank teller and is active in the feminist movement.

...About 85% to 95% of undergraduates at several major universities chose the second option, contrary to logic.

The word fallacy is used, in general, when people fail to apply a logical rule that is obviously relevant. Amos and I introduced the idea of a conjunction fallacy, which people commit when they judge a conjunction or two events to be more probable than one of the events in a direct comparison.

...The judgments of probability that our respondents offered, (in the Linda problem), corresponded precisely to the judgments of representativeness (similarity to stereotypes). Representativeness belongs to a cluster of closely related basic assessments that are likely to be generated together. The most representative outcomes combine with the personality description to produce the most coherent stories. The most coherent stories are not necessarily the most probable, but they are plausible, and the notions of coherence, plausibility, and probability are easily confused by the unwary.

* * *

From Max Bazerman's Judgment in Managerial Decision Making:

Which of the following instances appears most likely? Which appears second most likely?
A. Drawing a red marble from a bag containing 50 percent red marbles and 50 percent white marbles.

B. Drawing a red marble seven times in succession, with replacement (i.e., a selected marble is put back into the bag before the next marble is selected), from a bag containing 90 percent red marbles and 10 percent white marbles.

C. Drawing at least one red marble in seven tries, with replacement, from a bag containing 10 percent red marbles and 90 percent white marbles.

The most common ordering of preference is B-A-C. Interestingly, the correct order of likelihood is C (52%), A (50%), and B (48%). This result illustrates a general bias to overestimate the probability of conjunctive events, or events that must occur in conjunction with one another and to underestimate the probability of disjunctive events, or events that occur independently. Thus, when multiple events all need to occur (choice B) we overestimate the true likelihood of this happening, while if only one of many events needs to occur (choice C), we underestimate the true likelihood of this occurring.

The overestimation of conjunctive events offers a powerful explanation for the problems that typically occur with projects that require multistage planning. Individuals, businesses, and governments frequently fall victim to the conjunctive-events bias in terms of timing and budgets. Home remodelling, new product ventures, and public works projects seldom finish on time.

* * *

Astronomy Professor Carl Sagan said in Carl Sagan: A Life in the Cosmos: "The Chernobyl and Challenger disasters remind us that the highly visible technological systems in which enormous national prestige had been invested can nevertheless experience catastrophic failure."

Safety is a function of the total system – that is the interaction of all of the components. If only one component fails (and it need not be a key one), the system may fail. Assume an airplane has 2,000 independent parts or systems. Each part or system is designed to have a working probability of 99%. All the parts need to work together for the airplane to work, however the probability that at least one of the parts fails (causing the plane to malfunction) is 86%.

* * *

From Judgment and Decision Making, by Daniel Kahneman (1974):

Studies of choice among gamblers and of judgments of probability indicate that people tend to overestimate the probability of conjunctive events (Cohen, Chesnick, and Haran, 1972, 24) and to underestimate the probability of disjunctive events. These biases are readily explained as effects of anchoring.

The stated probability of the elementary event (success at any one stage) provides a natural starting point for the estimation of the probabilities of both conjunctive and disjunctive events. Since adjustment from the starting point is typically insufficient, the final estimates remain too close to the probabilities of the elementary events in both cases. Note the overall probability of a conjunctive event is lower than the probability of each elementary event, whereas the overall probability of a disjunctive event is higher than the probability of each elementary event. As a consequence of anchoring, the overall probability will be overestimated in conjunctive problems and underestimated in disjunctive problems.

Biases in the evaluation of compound events are particularly significant in the context of planning. The successful completion of an undertaking, such as the development of a new product or thesis, typically has a conjunctive character: for the undertaking to succeed, each of a series of events must occur. Even when each of these events is very likely, the overall probability of success can be quite low if the number of events is large.

The general tendency to overestimate the probability of conjunctive events leads to unwarranted optimism in the evaluation of the likelihood that a plan will success or that a project will be completed on time. Conversely, disjunctive structures are typically encountered in the evaluation of risks. A complex system, such as a nuclear reactor or the human body, will malfunction if any of its essential components fails. Even when the likelihood of failure in each component is slight, the probability of an overall failure can be high if many components are involved. Because of anchoring, people will tend to underestimate the probabilities of failure in complex systems. Thus, the direction of the anchoring bias can sometimes be inferred from the structure of the event. The chain-like structure of conjunctions leads to over-estimation, the funnel-like structure of disjunctions leads to underestimation.

** * **

Biases in the evaluation of compound events are particularly significant in the context of planning. Any complex undertaking has the character of a conjunctive event: lots of things have to click into place in order for the whole thing to work. Even when the probability of each individual event is very likely, the overall probability can be very low. People in general way overestimate the probability of the conjunctive event, leading to massive time and cost overruns in real projects.

Conversely, disjunctive structures are typically encountered in the evaluation of risks. A complex system, such as a nuclear reactor or a human body, will malfunction if just one key component fails. Even if the probability of failure of any one event is very low, the overall probability of some event going wrong is very high. People always underestimate the probability of complex systems, like the Challenger, going wrong. ([source](#))

28. Mental Model: Prisoners' Dilemma

The prisoners' dilemma is the best known strategy game in social science. The game shows why two entities might not cooperate even when it appears in their best (rational) interest to do so. What is rational for the individual in certain circumstances is not rational for the group — that is, pursuing a strategy that is rational for you leads to a worse outcome.

With applications to economics, politics, and business the game illustrates the conflict, which can sometimes arise, between individual and group rationality.

From Greg Mankiw's Economics textbook:

The prisoners' dilemma is a story about two criminals who have been captured by the police. Let's call them Mr Black and Mr Pink. The police have enough evidence to convict Mr Black and Mr Pink of a relatively minor crime, illegal possession of a handgun, so that each would spend a year in jail. The police also suspect that the two criminals have committed a jewelery robbery together, but they lack hard evidence to convict them of this major crime. The police question Mr Black and Mr Pink in separate rooms, and they offer each of them the following deal:

Right now we can lock you up for 1 year. If you confess to the jewelery robbery and implicate your partner, however, we'll give you immunity and you can go free. Your partner will get 20 years in jail. But if you both confess to the crime, we won't need your testimony and we can avoid the cost of a trial, so you will each get an intermediate sentence of 8 years.

If Mr Black and Mr Pink, heartless criminals that they are, care only about their own sentences, what would you expect them to do? Would they confess or remain silent? Each prisoner has two strategies: confess or remain silent. The sentence each prisoner gets depends on the strategy chosen by his or her partner in crime.

Consider first Mr Black's decision. He reasons as follows:

I don't know what Mr Pink is going to do. If he remains silent, my best strategy is to confess, since then I'll go free rather than spending a year in jail. If he confesses, my best strategy is still to confess, since then I'll spend 8 years in jail rather than 20. So, regardless of what Mr Pink does, I am better off confessing.

In the language of game theory, a strategy is called a dominant strategy if it is the best strategy for a player to follow regardless of the strategies pursued by other players. In this case, confessing is a dominant strategy for Mr Black. He spends less time in jail if he confesses, regardless of whether Mr Pink confesses or remains silent.

Now consider Mr Pink's decision. He faces exactly the same choices as Mr Black, and he reasons in much the same way. Regardless of what Mr Black does, Mr Pink can reduce his time in jail by confessing. In other words, confessing is a dominant strategy for Mr Pink. In the end, both Mr Black and Mr Pink confess, and both spend 8 years in jail. Yet, from their standpoint, this is a terrible outcome. If they had both remained silent, both of them would have been better off, spending only 1 year in jail on the gun charge. By each pursuing his own interests, the two prisoners together reach an outcome that is worse for each of them.

To see how difficult it is to maintain cooperation, imagine that, before the police captured Mr Black and Mr Pink, the two criminals had made a pact not to confess. Clearly, this agreement would make them both better off if they both live up to it, because they would each spend only 1 year in jail. But would the two criminals in fact remain silent, simply because they had agreed to? Once they are being questioned separately, the logic of self-interest takes over and leads them to confess. Cooperation between the two prisoners is difficult to maintain because cooperation is individually irrational.

* * *

Michael J. Mauboussin writes:

The classic two-player example of game theory is the prisoners' dilemma. We can recast the prisoners' dilemma in a business context by considering a simple case of capacity addition. Say two competitors, A and B, are considering adding capacity. If competitor A adds capacity and B doesn't, A gets an outsized payoff. Likewise, if B adds capacity and A doesn't than B gets the large payoff. If neither expands, A and B aren't as well-off as if one alone had added capacity. But if both add capacity, they're worse off of than if they had done nothing.

** * **

Avinash Dixit offers:

Consider two firms, say Coca-Cola and Pepsi, selling similar products. Each must decide on a pricing strategy. They best exploit their joint market power when both charge a high price; each makes a profit of ten million dollars per month. If one sets a competitive low price, it wins a lot of customers away from the rival. Suppose its profit rises to twelve million dollars, and that of the rival falls to seven million. If both set low prices, the profit of each is nine million dollars. Here, the low-price strategy is akin to the prisoner's confession, and the high-price akin to keeping silent. Call the former cheating, and the latter cooperation. Then cheating is each firm's dominant strategy, but the result when both "cheat" is worse for each than that of both cooperating.

** * **

Warren Buffett provides some illumination as to how the Prisoners' Dilemma plays out in business in the 1985 Berkshire Hathaway Annual report.

The domestic textile industry operates in a commodity business, competing in a world market in which substantial excess capacity exists. Much of the trouble we experienced was attributable, both directly and indirectly, to competition from foreign countries whose workers are paid a small fraction of the U.S. minimum wage. But that in no way means that our labor force deserves any blame for our closing. In fact, in comparison with employees of American industry generally, our workers were poorly paid, as has been the case throughout the textile business. In contract negotiations, union leaders and members were sensitive to our disadvantageous cost position and did not push for unrealistic wage increases or unproductive work practices. To the contrary, they tried just as hard as we did to keep us competitive. Even during our liquidation period they performed superbly. (Ironically, we would have been better off financially if our union had behaved unreasonably some years ago; we then would have recognized the impossible future that we faced, promptly closed down, and avoided significant future losses.)

Over the years, we had the option of making large capital expenditures in the textile operation that would have allowed us to somewhat reduce variable costs. Each proposal to do so looked like an immediate winner. Measured by standard return-on-investment tests, in fact, these proposals usually promised greater economic benefits than would have resulted from comparable expenditures in our highly-profitable candy and newspaper businesses.

But the promised benefits from these textile investments were illusory. Many of our competitors, both domestic and foreign, were stepping up to the same kind of expenditures and, once enough companies did so, their reduced costs became the baseline for reduced prices industry-wide. Viewed individually, each company's capital investment decision appeared cost-effective and rational; viewed collectively, the decisions neutralized each other and were irrational (just as happens when each person watching a parade decides he can see a little better if he stands on tiptoes). After each round of investment, all the players had more money in the game and returns remained anemic.

Thus, we faced a miserable choice: huge capital investment would have helped to keep our textile business alive, but would have left us with terrible returns on ever-growing amounts of capital. After the investment, moreover, the foreign competition would still have retained a major, continuing advantage in labor costs. A refusal to invest, however, would

make us increasingly non-competitive, even measured against domestic textile manufacturers. I always thought myself in the position described by Woody Allen in one of his movies: "More than any other time in history, mankind faces a crossroads. One path leads to despair and utter hopelessness, the other to total extinction. Let us pray we have the wisdom to choose correctly."

For an understanding of how the to-invest-or-not-to-invest dilemma plays out in a commodity business, it is instructive to look at Burlington Industries, by far the largest U.S. textile company both 21 years ago and now. In 1964 Burlington had sales of \$1.2 billion against our \$50 million. It had strengths in both distribution and production that we could never hope to match and also, of course, had an earnings record far superior to ours. Its stock sold at 60 at the end of 1964; ours was 13.

Burlington made a decision to stick to the textile business, and in 1985 had sales of about \$2.8 billion. During the 1964-85 period, the company made capital expenditures of about \$3 billion, far more than any other U.S. textile company and more than \$200-per-share on that \$60 stock. A very large part of the expenditures, I am sure, was devoted to cost improvement and expansion. Given Burlington's basic commitment to stay in textiles, I would also surmise that the company's capital decisions were quite rational.

Nevertheless, Burlington has lost sales volume in real dollars and has far lower returns on sales and equity now than 20 years ago. Split 2-for-1 in 1965, the stock now sells at 34 — on an adjusted basis, just a little over its \$60 price in 1964. Meanwhile, the CPI has more than tripled. Therefore, each share commands about one-third the purchasing power it did at the end of 1964. Regular dividends have been paid but they, too, have shrunk significantly in purchasing power.

This devastating outcome for the shareholders indicates what can happen when much brain power and energy are applied to a faulty premise. The situation is suggestive of Samuel Johnson's horse: "A horse that can count to ten is a remarkable horse — not a remarkable mathematician." Likewise, a textile company that allocates capital brilliantly within its industry is a remarkable textile company — but not a remarkable business.

My conclusion from my own experiences and from much observation of other businesses is that a good managerial record (measured by economic returns) is far more a function of what business boat you get into than it is of how effectively you row (though intelligence and effort help considerably, of course, in any business, good or bad). Some years ago I wrote: "When a management with a reputation for brilliance tackles a business with a reputation for poor fundamental economics, it is the reputation of the business that remains intact." Nothing has since changed my point of view on that matter. Should you find yourself in a chronically-leaking boat, energy devoted to changing vessels is likely to be more productive than energy devoted to patching leaks.

** * **

Mauboussin adds:

Our discussion so far has focused on competition. But thoughtful strategic analysis also recognizes the role of co-evolution, or cooperation, in business. Not all business relationships are conflictual. Sometimes companies outside the purview of a firm's competitive set can heavily influence its value creation prospects.

Consider the example of DVD makers (software) and DVD player makers (hardware). These companies do not compete with one another. But the more DVD titles that are available, the more attractive it will be for a consumer to buy a DVD player and vice versa. Another example is the Wintel standard—added features on Microsoft's operating system required more powerful Intel microprocessors, and more powerful microprocessors could support updated operating systems. Complementors make the added value pie bigger. Competitors fight over a fixed pie.

** * **

Mankiw offers another real world example:

Consider an oligopoly with two members, called Iran and Saudi Arabia. Both countries sell crude oil. After prolonged negotiation, the countries agree to keep oil production low in order to keep the world price of oil high. After they agree on production levels, each country must decide whether to cooperate and live up to this agreement or to ignore it and produce at a higher level. The following image shows how the profits of the two countries depend on the strategies they choose.

Suppose you are the leader of Saudi Arabia. You might reason as follows:

I could keep production low as we agreed, or I could raise my production and sell more oil on world markets. If Iran lives up to the agreement and keeps its production low, then my country earns profit of \$60 billion with high production and \$50 billion with low production. In this case, Saudi Arabia is better off with high production. If Iran fails to live up to the agreement and produces at a high level, then my country earns \$40 billion with high production and \$30 billion with low production. Once again, Saudi Arabia is better off with high production. So, regardless of what Iran chooses to do, my country is better off reneging on our agreement and producing at a high level.

Producing at a high level is a dominant strategy for Saudi Arabia. Of course, Iran reasons in exactly the same way, and so both countries produce at a high level. The result is the inferior outcome (from both Iran and Saudi Arabia's standpoint) with low profits in each country.

This example illustrates why oligopolies have trouble maintaining monopoly profits. The monopoly outcome is jointly rational for the oligopoly, but each oligopolist has an incentive to cheat. Just as self-interest drives the prisoners in the prisoners' dilemma to confess, self-interest makes it difficult for the oligopoly to maintain the cooperative outcome with low production, high prices and monopoly prices.

29. Former Canadian Prime Minister Mackenzie King on The Law of Competing Standards

I came across that passage while reading “Industry and Humanity,” by former Canadian Prime Minister Mackenzie King. We’ll add this to our previous knowledge on Gresham’s Law.

In the reign of Queen Elizabeth, an official named Gresham observed that where different metals were in circulation as coinage and some were better than others of the same nominal value, the coins made of the inferior metal tended to drive the better out of circulation. The better coins were either hoarded or melted down and sold as bullion, were used in the fine arts, or were absorbed in the foreign exchanges. In other words, what Gresham discovered was that cheaper money tends to drive out dearer; that when people begin to discriminate between two coinages, they will invariably pay out the inferior and hoard the better, thus removing the better from circulation. This phenomenon once generally observed came to be described as a “Law,” and was identified with Gresham’s name, since it was Gresham who was first successful in drawing public attention to it. Amongst money-changers, Gresham’s Law of the precious metals is better known than the Ten Commandments.

Something analogous to Gresham’s Law will be found to obtain in the case of competing standards in Industry. Assuming there is indifference in the matter of choice between competing commodities or services, but that in the case of such commodities or services the labor standards involved vary, the inferior standard, if brought in this manner into competition with a higher standard, will drive it out, or drag the higher down to its level. This is effected by the opportunity of under-selling which comes, where in such cases human well-being is sacrificed to material ends. The superior standard, not being recognized or demanded, is unable to hold its own, and in time disappears. This Law is just as real and relentless in its operation in Industry as Gresham’s Law of the precious metals is with respect to money and the mechanism of exchange. Indeed, a more accurate exposition would describe both as manifestations of one and the same law, which I propose to call the Law of Competing Standards. I see no reason why economists should not recognize the existence of such a law, and incorporate it immediately in economic science as being quite as significant as the Law of Supply and Demand, the Law of Diminishing Returns, or any other Law accorded a place in its nomenclature.

The Law of Competing Standards is doubtless a part of the general Law of Competition, under which the cheaper of two commodities gains in competition a preference over the dearer. What Gresham discovered was an important sequence of the Law of Competition as applied to coinage; namely, the disappearance, in the course of time, of the superior metals. Observance of a like sequence in the case of standards in Industry is highly desirable. As respects labor standards, I believe that recognition of the operation of the Law of Competing Standards over ever-widening areas would do more than aught else to clear up the most baffling problems with which Industry is confronted, and to point the way to a solution of many situations which hitherto have seemed incapable of solution.

30. Daniel Kahneman and Herbert Simon on Intuition

Why do experts seem to have better intuition than the rest of us when operating within their Circle of Competence?

Are they doing something the rest of us are not? Or is there another explanation that unlocks the keys of intuition.

In *Thinking Fast and Slow*, Nobel laureate Daniel Kahneman writes that “intuition is nothing more and nothing less than recognition.”

When we experience something either *directly* (first hand) or *indirectly* (we’ve read about it or hear it in a podcast) our brains take note and file it away. Later when we encounter a situation that resembles our chunk, our brains leap into a subconscious recognition of a situation. Our intuition about the situation might be correct and it might be wrong but it’s not operating at the level of conscious thought. You can think of intuition as thinking that you know something without really knowing how or why you know it.

When Can We Trust Our Intuition?

While our intuition is often right, it also leads us astray. Without consciously realizing it we place a high confidence in our intuition. And why wouldn’t we? It’s right far more often than it’s wrong. But confidence is a poor proxy for correctness and often means that when you’re wrong, you’re really wrong. Luckily there are situations where our intuition is more likely to be right than others.

Our intuition is more often right if:

1. The environment is unchanging or slow to change. Complex adaptive systems are poor places to develop intuition.
2. We have a large sample size. That is., we get a lot of practice.
3. We receive immediate and accurate feedback.

So all we need is an unchanging environment, lots of practice, and immediate feedback. Simple but not easy. If any of those things are not true, we should rely less on our subconscious gut and more on our rational brain.

The Components of Expertise

This connects with something Herbert Simon, another Nobel laureate, wrote on expertness and intuition:

We have seen that a major component of expertise is the ability to recognize a very large number of specific relevant cues when they are present in any situation, and then to retrieve from memory information about what to do when those particular cues are noticed. Because of this knowledge and recognition capability, experts can respond to new situations very rapidly—and usually with considerable accuracy. Of course, on further thought, the initial reaction may not be the correct one, but it is correct in a substantial number of cases and is rarely irrelevant.

Chess grandmasters, looking at the chessboard, will generally form a hypothesis about the best move within five seconds, and in four out of five cases, this initial hypothesis will be the move they ultimately prefer. Moreover, it can be shown that this ability accounts for a very large proportion of their chess skill. For, if required to play very rapidly, the grandmaster may not maintain a grandmaster level of play but will almost always maintain a master level, even though in rapid play there is time for almost nothing but to react to the first cues that are noticed on the board.

We usually use the word “intuition” – sometimes also “judgment” or even “creativity” – to refer to this ability of experts to respond to situations in their domains of expertise almost instantaneously and relatively accurately.

In his autobiography, *Models of My Life*, Simon further elaborates on the difference between expert decision makers and the rest of us.

The decision maker of experience has at his disposal a checklist of things to watch out for before finally accepting a decision. A large part of the difference between the experienced decision maker and the novice in these situations is not any particular intangible like "judgment" or "intuition." If one could open the lid, so to speak, and see what was in the head of the experienced decision-maker, one would find that he had at his disposal repertoires of possible actions; that he had checklists of things to think about before he acted; and that he had mechanisms in his mind to evoke these, and bring these to his conscious attention when the situations for decisions arose.

31. Why Do People Choke When the Stakes Are High?

Loss Aversion.

In sports, on a game show, or just on the job, what causes people to choke when the stakes are high? A new study by researchers at the California Institute of Technology (Caltech) suggests that when there are high financial incentives to succeed, people can become so afraid of losing their potentially lucrative reward that their performance suffers. It is a somewhat unexpected conclusion. After all, you would think that the more people are paid, the harder they will work, and the better they will do their jobs — until they reach the limits of their skills. That notion tends to hold true when the stakes are low, says Vikram Chib, a postdoctoral scholar at Caltech and lead author on a paper published in the May 10 issue of the journal Neuron. Previous research, however, has shown that if you pay people too much, their performance actually declines.

Some experts have attributed this decline to too much motivation: they think that, faced with the prospect of earning an extra chunk of cash, you might get so excited that you will fail to do the task properly. But now, after looking at brain-scan data of volunteers performing a specific motor task, the Caltech team says that what actually happens is that you become worried about losing your potential prize. The researchers also found that the more someone is afraid of loss, the worse they perform.

32. The Basic Laws of Human Stupidity

Carlo Cipolla, a former Professor of Economics at UC Berkeley, lists the basic laws of human stupidity:

The first basic law of human stupidity asserts without ambiguity that: Always and inevitably everyone underestimates the number of stupid individuals in circulation.

At first, the statement sounds trivial, vague and horribly ungenerous. Closer scrutiny will however reveal its realistic veracity. No matter how high are one's estimates of human stupidity, one is repeatedly and recurrently startled by the fact that:

a) people whom one had once judged rational and intelligent turn out to be unashamedly stupid.

b) day after day, with unceasing monotony, one is harassed in one's activities by stupid individuals who appear suddenly and unexpectedly in the most inconvenient places and at the most improbable moments.

The First Basic Law prevents me from attributing a specific numerical value to the fraction of stupid people within the total population: any numerical estimate would turn out to be an underestimate. Thus in the following pages I will denote the fraction of stupid people within a population by the symbol σ .

33. Batesian Mimicry: Why Copycats Are Successful

One of our first interview guests for The Knowledge Project was the former NFL executive Michael Lombardi. In our interview, we discussed topics ranging from the nature of leadership to decision making in a football context. Mike is one of the wisest thinkers associated with the game.

We heard Mike on an NFL podcast recently, and in a brief clip you can listen to here, Mike makes a fascinating comment on differentiating between a Mimic and the Real Thing:

“There’s two kinds of snakes you come across. There’s the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it’s venomous, it can kill you in a minute. The Mexican Milk Snake can’t do anything to you; it’s an impostor.”

Mike got the idea from my friend and CEO of Glenair, Peter Kaufman. Following Mike’s lead, we chose to dig in a little further.

Turns out there are a *host* of Coral Snake Mimics, all designed to look exactly as fierce as the true bad guys. Besides the Mexican Milk Snake, there is the Scarlet King Snake, the Florida Scarlet Snake, and the California Mountain Kingsnake. (At least.)

For an example, here are the Texas Coral Snake on the left and the Mexican Milk Snake on the right. Pretty damn close!

According to Wikipedia, the Texas Coral Snake's venom is a "powerful neurotoxin, causing neuromuscular dysfunction", and terrifyingly describes its bite as coming from "a pair of hollow, small, fixed fangs in the front of its upper jaw, through which the venom is injected and encouraged via a chewing motion. Due to this method of venom delivery, a coral snake must bite and hold on for a brief time to deliver a significant amount of venom..." The Milk Snake, on the other hand, is described as a pretty ideal pet: "The Mexican Milk Snake adapts well to captive care, and its smaller size and striking colorations can make it an attractive choice for a pet snake. They are normally docile, and not typically apt to bite or expel musk."

So, how is it that these two look alike? It's due to a phenomenon called Batesian Mimicry. In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the "models") were able to operate freely and relatively unmolested, there had also developed a "mimic" population of butterflies which wasn't toxic at all, yet still went untouched!

In fact, biologists eventually figured out that the more toxic and dangerous the "model" was and the more frequently they appeared in the local population, the easier it was for its "mimics" to get by! Predators simply wouldn't take the risk of mixing up the two. If there aren't as many "models" around or they aren't that dangerous, the mimics have a harder time.

This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or "pretenders to the throne" are often very effective, very convincing "mimics" of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs.

We see a very Batesian effect at work: The more impressive the "model," the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many "future" Warren Buffetts. For every Steve Jobs, there have been many "next" Steve Jobs'. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit.

It seems almost a law of nature that success will be copied, sometimes in a very disgraceful way. (Charlie Munger thinks that the fundamental algorithm of life is "Repeat what works.")

Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry — even in ourselves.

This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself.

The real thing knows a fake. Charlie Munger once commented on this in relation to the field of money management:

"It's very hard to tell the difference between a good money manager and someone who just has the patter down. If you aren't a good money manager yourself, rather than trying to pick one, you're probably better off with a low cost index fund. 'It takes one to know one'."

An insight this good is only possible through continued study across the largest and most relevant fields of study. Peter got this idea by studying biology, a field full of incredible insight but, strangely underappreciated by most "non-biologists". It's not just ideas about predators and prey, but niches, competition, co-evolutionary arms races and a whole host of others which give us massive insight into the human world.

Peter realized that studying across fields like biology and physics is something like buying an index fund: It works because you capture *all* the important companies traded on the public exchange, not just a select few. That means you capture the massive winners, which tend to greatly outweigh the failures.

Studying across *all* of the important fields gives you the same advantage, except it's even better: If an index fund buys a new position, it must sell something to do so; consequently, the "big winners" can only impact your portfolio in a limited way. But if you come to understand a new Great Idea, you don't have to give up the ones you already know! This is a great advantage.

And so it's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

If you liked this post, you'll probably also love:

The Need for Biological Thinking to Solve Complex Problems — How should we think about complexity? Should we use a biological or physics system? The answer, of course, is that it depends. It's important to have both tools available at your disposal.

The Founder Principle: A Wonderful Idea from Biology — In his brilliant *The Song of the Dodo*, David Quammen gives us not only the stories of many brilliant biological naturalists including Mayr, but we also get a deep dive into the core concepts of evolution and extinction, including the Founder Effect.

Biology Enables. Culture Forbids. — From a biological perspective, nothing is unnatural. Whatever is possible is by definition also natural.

34. The Need for Biological Thinking to Solve Complex Problems

“Biological thinking and physics thinking are distinct, and often complementary, approaches to the world, and ones that are appropriate for different kinds of systems.”

How should we think about complexity? Should we use a biological or physics system? The answer, of course, is that it depends. It's important to have both tools available at your disposal.

These are the questions that Samuel Arbesman explores in his fascinating book Overcomplicated: Technology at the Limits of Comprehension.

[B]iological systems are generally more complicated than those in physics. In physics, the components are often identical—think of a system of nothing but gas particles, for example, or a single monolithic material, like a diamond. Beyond that, the types of interactions can often be uniform throughout an entire system, such as satellites orbiting a planet.

Biology is different, and there is something meaningful to be learned from a biological approach to thinking.

In biology, there are a huge number of types of components, such as the diversity of proteins in a cell or the distinct types of tissues within a single creature; when studying, say, the mating behavior of blue whales, marine biologists may have to consider everything from their DNA to the temperature of the oceans. Not only is each component in a biological system distinctive, but it is also a lot harder to disentangle from the whole. For example, you can look at the nucleus of an amoeba and try to understand it on its own, but you generally need the rest of the organism to have a sense of how the nucleus fits into the operation of the amoeba, how it provides the core genetic information involved in the many functions of the entire cell.

Arbesman makes an interesting point here when it comes to how we should look at technology. As the interconnections and complexity of technology increases, it increasingly resembles a biological system rather than a physics one. There is another difference.

[B]iological systems are distinct from many physical systems in that they have a history. Living things evolve over time. While the objects of physics clearly do not emerge from thin air—astrophysicists even talk about the evolution of stars—biological systems are especially subject to evolutionary pressures; in fact, that is one of their defining features. The complicated structures of biology have the forms they do because of these complex historical paths, ones that have been affected by numerous factors over huge amounts of time. And often, because of the complex forms of living things, where any small change can create unexpected effects, the changes that have happened over time have been through tinkering: modifying a system in small ways to adapt to a new environment.

Biological systems are generally hacks that evolved to be good enough for a certain environment. They are far from pretty top-down designed systems. And to accommodate an ever-changing environment, they are rarely the most optimal system on a micro-level, preferring to optimize for survival over any one particular attribute. And it's not the survival of the individual that's optimized, it's the survival of the species.

Technologies can appear robust until they are confronted with some minor disturbance, causing a catastrophe. The same thing can happen to living things. For example, humans can adapt incredibly well to a large array of environments, but a tiny change in a person's genome can cause dwarfism, and two copies of that mutation invariably cause death. We are of a different scale and material from a particle accelerator or a computer network, and yet these systems have profound similarities in their complexity and fragility.

Biological thinking, with a focus on details and diversity, is a necessary tool to deal with complexity.

The way biologists, particularly field biologists, study the massively complex diversity of organisms, taking into account their evolutionary trajectories, is therefore particularly appropriate for understanding our technologies. Field biologists often act as naturalists—collecting, recording, and cataloging what they find around them—but even more than that, when confronted with an enormously complex ecosystem, they don't immediately try to understand it all in its totality. Instead, they recognize that they can study only a tiny part of such a system at a time, even if imperfectly. They'll look at the interactions of a handful of species, for example, rather than examine the complete web of species within a single region. Field biologists are supremely aware of the assumptions they are making, and know they are looking at only a sliver of the complexity around them at any one moment. [...]

When we're dealing with different interacting levels of a system, seemingly minor details can rise to the top and become important to the system as a whole. We need "Field biologists" to catalog and study details and portions of our complex systems, including their failures and bugs. This kind of biological thinking not only leads to new insights, but might also be the primary way forward in a world of increasingly interconnected and incomprehensible technologies.

Waiting and observing isn't enough.

Biologists will often be proactive, and inject the unexpected into a system to see how it reacts. For example, when biologists are trying to grow a specific type of bacteria, such as a variant that might produce a particular chemical, they will resort to a process known as mutagenesis. Mutagenesis is what it sounds like: actively trying to generate mutations, for example by irradiating the organisms or exposing them to toxic chemicals.

When systems are too complex for human understanding, often we need to insert randomness to discover the tolerances and limits of the system. One plus one doesn't always equal two when you're dealing with non-linear systems. For biologists, tinkering is the way to go.

As Stewart Brand noted about legacy systems, "Teasing a new function out of a legacy system is not done by command but by conducting a series of cautious experiments that with luck might converge toward the desired outcome."

When Physics and Biology Meet

This doesn't mean we should abandon the physics approach, searching for underlying regularities in complexity. The two systems complement one another rather than compete. Arbesman recommends asking the following questions:

When attempting to understand a complex system, we must determine the proper resolution, or level of detail, at which to look at it. How fine-grained a level of detail are we focusing on? Do we focus on the individual enzyme molecules in a cell of a large organism, or do we focus on the organs and blood vessels? Do we focus on the binary signals winding their way through circuitry, or do we examine the overall shape and function of a computer program? At a larger scale, do we look at the general properties of a computer network, and ignore the individual machines and decisions that make up this structure?

When we need to abstract away a lot of the details and lean on physics thinking more.

Think about it from an organizational perspective. The new employee at the lowest level is focused on the specific details of their job, whereas the executive is focused on systems, strategy, culture, and flow — how things interact and reinforce one another. The details of the new employee's job are lost on them.

We can't use one system, whether biological or physics, exclusively. That's fragile thinking. Instead, we need to combine both systems.

In Cryptonomicon, a novel by Neal Stephenson, he makes exactly this point talking about the structure of the pantheon of Greek gods:

And yet there is something about the motley asymmetry of this pantheon that makes it more credible. Like the Periodic Table of the Elements or the family tree of the elementary particles, or just about any anatomical structure that you might pull up out of a cadaver, it has enough of a pattern to give our minds something to work on and yet an irregularity that indicates some kind of organic provenance—you have a sun god and a moon goddess, for example, which is all clean and symmetrical, and yet over here is Hera, who has no role whatsoever except to be a literal bitch goddess, and then there is Dionysus who isn't even fully a god—he's half human—but gets to be in the Pantheon anyway and sit on Olympus with the Gods, as if you went to the Supreme Court and found Bozo the Clown planted among the justices.

35. The Founder Principle: A Wonderful Idea from Biology

We've all been taught natural selection; the mechanism by which species evolve through differential reproductive success. Most of us are familiar with the idea that random mutations in DNA cause variances in offspring, some of which survive more frequently than others. However, this is only part of the story.

Sometimes other situations cause massive changes in species populations, and they're often more nuanced and tough to spot.

One such concept comes from one of the most influential biologists in history, Ernst Mayr. He called it The Founder Principle, a mechanism by which new species are created by a splintered population; often with lower genetic diversity and an increased risk of extinction. In the brilliant The Song of the Dodo: Island Biography in an Age of Extinction, David Quammen gives us not only the stories of many brilliant biological naturalists including Mayr, but we also get a deep dive into the core concepts of evolution and extinction, including the founder principle.

Quammen begins by outlining the basic idea:

When a new population is founded in an isolated place, the founders usually constitute a numerically tiny group – a handful of lonely pioneers, or just a pair, or maybe no more than one pregnant female. Descending from such a small number of founders, the new population will carry only a minuscule and to some extent random sample of the gene pool of the base population. The sample will most likely be unrepresentative, encompassing less genetic diversity than the larger pool. This effect shows itself whenever a small sample is taken from a large aggregation of diversity; whether the aggregation consists of genes, colored gum balls, M&M's, the cards of a deck, or any other collection of varied items, a small sample will usually contain less diversity than the whole.

Why does the founder principle happen? It's basically applied probability. Perhaps an example will help illuminate the concept.

Think of yourself playing a game of poker (five card draw) with a friend. The deck of cards is separated into four suits: Diamonds, hearts, clubs and spades, each suit having 13 cards for a total of 52 cards.

Now look at your hand of five cards. Do you have one card from each suit? Maybe. Are all five cards from the same suit? Probably not, but it is possible. Will you get the ace of spades? Maybe, but not likely.

This is a good metaphor for how the founder principle works. The gene pool carried by a small group of founders is unlikely to be precisely representative of the gene pool of the larger group. In some rare cases it will be very unrepresentative, like you getting dealt a straight flush.

It starts to get interesting when this founder population starts to reproduce, and genetic drift causes the new population to diverge significantly from its ancestors. Quammen explains:

Already isolated geographically from its base population, the pioneer population now starts drifting away genetically. Over the course of generations, its gene pool becomes more and more different from the gene pool of the base population – different both as to the array of alleles (that is, the variant forms of a given gene) and as to the commonness of each allele.

The founder population, in some cases, will become so different that it can no longer mate with the original population. This new species may even be a competitor for resources if the two populations are ever reintroduced. (Say, if a land bridge is created between two islands, or humans bring two species back in contact.)

Going back to our card metaphor, let's pretend that you and your friend are playing with four decks of cards — 208 total cards. Say we randomly pulled out forty cards from those decks. If there are absolutely no kings in the forty cards you are playing with, you will

never be able to create a royal flush (ace+king+queen+jack+10 of the same suit). It doesn't matter how the cards are dealt, you can never make a royal flush with no kings. Thus it is with species: If a splintered-off population isn't carrying a specific gene variant (allele), that variant can never be represented in the newly created population, no matter how prolific that gene may have been in the original population. It's gone. And as the rarest variants disappear, the new population becomes increasingly unlike the old one, especially if the new population is small.

Some alleles are common within a population, some are rare. If the population is large, with thousands or millions of parents producing thousands or millions of offspring, the rare alleles as well as the common ones will usually be passed along. Chance operation at high numbers tends to produce stable results, and the proportions of rarity and commonness will hold steady. If the population is small, though, the rare alleles will most likely disappear [...] As it loses its rare alleles by the wayside, a small pioneer population will become increasingly unlike the base population from which it derived.

Some of this genetic loss may be positive (a gene that causes a rare disease may be missing), some may be negative (a gene for a *useful* attribute may be missing) and some may be neutral.

The neutral ones are the most interesting: A neutral gene at one point in time may become a useful gene at another point. It's like playing a round of poker where 8's are suddenly declared "wild," and that card suddenly becomes much more important than it was the hand before. The same goes for animal traits.

Take a mammal population living on an island, having lost all of its ability to swim. That won't mean much if all is well and it is never *required* to swim. But the moment there is a natural disaster such as a fire, having the ability to swim the short distance to the mainland could be the difference between survival or extinction.

That's why the founder principle is so dangerous: The loss of genetic diversity often means losing valuable survival traits. Quammen explains:

Genetic drift compounds the founder-effect problem, stripping a small population of the genetic variation that it needs to continue evolving. Without that variation, the population stiffens toward uniformity. It becomes less capable of adaptive response. There may be no manifest disadvantages in uniformity so long as environmental circumstances remain stable; but when circumstances are disrupted, the population won't be capable of evolutionary adjustment. If the disruption is drastic, the population may go extinct.

This loss of adaptability is one of the two major issues caused by the founder principle, the second being inbreeding depression. A founder population may have no choice but to only breed within its population and a symptom of too much inbreeding is the manifestation of harmful genetic variants among inbred individuals. (One reason humans consider incest a dangerous activity.) This too increases the fragility of species and decreases their ability to evolve.

The founder principle is just one of many amazing ideas in The Song of the Dodo. In fact, we at Farnam Street feel the book is so important that it made our list of books we recommend to improve your general knowledge of the world and it was the first book we picked for our members-only reading group.

If you have already read this book and want more we suggest Quammen's The Reluctant Mr. Darwin or his equally thought provoking Spillover: Animal Infections and the Next Human Pandemic. Another wonderful and readable book on species evolution is The Beak of the Finch, by Jonathan Weiner.

36. What Biology Enables, Culture Forbids

We get a little confused when deciding if a particular human behavior is cultural or biological. Is homosexuality a natural act or unnatural? How about Facebook? Is it unnatural human behavior? Abortion? Non-procreative sex? Slavery? Mixing of races? Many of these are either explicitly or certainly border on being taboo subjects. As in, they may not be discussed in polite company, even when encouraged.

Yet, for those of us seeking to understand reality as it is, to understand deeply the most important buckets of knowledge, taboo is no reason to avoid the hard subjects.

So how should we think about this?

“From a biological perspective, nothing is unnatural. Whatever is possible is by definition also natural.”

— Yuval Harari

Professor Yuval Harari, who has previously taught us why humans dominate the earth and the false natural state of man, has an interesting take, discussed in his book Sapiens: A Brief History of Humankind. The chapter is aptly titled “There is No Justice in History.”

Professor Harari’s well-informed heuristic boils down to: Biology Enables. Culture Forbids. *How can we distinguish what is biologically determined from what people merely try to justify through biological myths? A good rule of thumb is ‘Biology enables, culture forbids.’ Biology is willing to tolerate a very wide spectrum of possibilities. It’s culture that obligates people to realize some possibilities while forbidding others. Biology enables women to have children — some cultures oblige women to realize this possibility. Biology enables men to enjoy sex with one another — some cultures forbid them to realize this possibility. Culture tends to argue that it forbids only that which is unnatural. But from a biological perspective, nothing is unnatural. Whatever is possible is by definition also natural. A truly unnatural behavior, one that goes against the laws of nature, simply cannot exist, so it would need no prohibition.*

[...]

...Evolution has no purpose. Organs have not evolved with a purpose, and the way they are used is in constant flux. There is not a single organ in the human body that only does the job its prototype did when it first appeared hundreds of millions of years ago. Organs evolve to perform a particular function, but once they exist, they can be adapted for other usages as well. Mouths, for example, appeared because the earliest multicellular organisms needed a way to take nutrients into their bodies. We still use our mouths for that purpose, but we also use them to kiss, speak, and, if we are Rambo, to pull the pins out of hand grenades. Are any of these uses unnatural simply because our worm-like ancestors 600 million years ago didn’t do those things with their mouths?

Our biology gives us a very wide playground and a lot of berth. We’re capable of a wide variety of activities and forms of organization, while other species generally fall into far more fixed and predictable hierarchies.

Over the course of history, humans have taken advantage of this wide range in a variety of positive and negative ways by creating and sustaining myths not supported by biological reality.

Take slavery, once a common practice throughout the world and now thankfully considered a scourge (and illegal) on all parts of the planet. Or the caste system, still in place in some in certain areas of the world, although perhaps less strictly than in the past.

Both slavery and the castes were carried out through a series of pseudoscientific rationalizations about the “natural order” of things, stories strong enough to be believed (in part) by all constituents of the hierarchy. This “forbidding” aspect of culture was not supported by biological differences, but that didn’t make the stories any less powerful or believable.

Even the American political system, ostensibly founded on a bedrock of “liberty and equality”, only provided those things to certain small groups. The Founders used cultural myths to rationalize a deeply divided society in which men had dominion over women, European whites had dominion over blacks and the native people, and the historically rich had dominion over the historically poor. Any other order would have been “unnatural”: *The American order consecrated the hierarchy between the rich and poor. Most Americans at that time had little problem with the inequality caused by wealthy parents passing their money and businesses onto their children. In their view, equality meant simply that the same laws applied to rich and poor. It had nothing to do with unemployment benefits, integrated education or health insurance. Liberty, too, carried very different connotations than it does today. In 1776, it did not mean that the disempowered (certainly not blacks or Indians or, God forbid, women) could gain and exercise power. It meant simply that the state could not, except in unusual circumstances, confiscate a citizen’s private property or tell him what to do with it. The American order thereby upheld the hierarchy of wealth, which some thought was mandated by God and others viewed representing the immutable laws of nature. Nature, it was claimed, rewarded merit with wealth while penalizing indolence.*

All the above-mentioned distinctions — between free persons and slaves, between whites and blacks, between rich and poor — are rooted in fictions... Yet it is an iron rule of history that every imagined hierarchy disavows its fictional origins and claims to be natural and inevitable. For instance, many people who have viewed the hierarchy of free persons and slaves as natural and correct have argued that slavery is not a human invention. Hammurabi saw it as ordained by the gods. Aristotle argued that slaves have a ‘slavish nature’ whereas free people have a ‘free nature’. Their status in society is merely a reflection of their innate nature.

This isn’t to argue that there aren’t biological differences between certain groups of people, including men and women. There are. But history has shown our tendency to exaggerate those differences and to create stories around our exaggerations, stories that uphold a certain desired hierarchy. These stories have a way of creating their own reality.

Just as frequently, we commit the opposite sin by restricting certain behavior based on some idea of what’s “natural” or “unnatural”, confusing biology with religious or cultural taboos. (And these myths die hard: It’s hard to fathom, but homosexuality wasn’t even legal in the United Kingdom until 1967.) As Harari rightly points out, anything we can do is perfectly natural in the biological sense. We come well-equipped for a variety of behavior. And this certainly isn’t to argue that all behavior is equally acceptable: We put bumpers on society to reduce murder, rape, slavery, and other vile behavior that is perfectly biologically natural to us, and we should.

But unless we recognize the difference between biology and cultural myth and seek to reduce our unfair taboos wherever possible, we fail in some way to see the world through the eyes of others, and see that our imagined order is not always a fair or just one, a natural or inevitable one. Maybe some of the things we see around us are just a historical accident if we look closely enough.

Even more than that, examining the relationship between biological reality and cultural myth allows us to appreciate our basic storytelling instincts. Human beings are wired for narrative: We’ve been called the Storytelling Animal and for good reason. Our thirst and ready acceptance of narrative is a basic part of our existence; it’s hard-wired into our genetic algorithm.

Much of our narrative superpower can be observed in the structure of human language, which is unique among species in its infinite flexibility and adaptability. It makes us capable of great cooperative accomplishments, but also great evils.

Fortunately, the modern world has done a pretty good job steadily loosening the grip of mythical “natural” realities that only exist in our heads. But a fair inquiry remains: What sustaining myths still exist? Are they for good or for evil? We leave that for you to ponder.

37. The Red Queen Effect: Avoid Running Faster to Stay in the Same Place

Charles Lutwidge Dodgson (1832-1898), better known by his pseudonym Lewis Carroll, was not only an author but a keen observer of human nature. His most famous works are *Alice's Adventures in Wonderland* and its sequel *Through the Looking Glass*, which have become timeless classics.

Bees have to move very fast to stay still.

David Foster Wallace

In *Through the Looking Glass*, Alice, a young girl, gets schooled by the Red Queen in an important life lesson that many of us fail to heed. Alice finds herself running faster and faster but staying in the same place.

Alice never could quite make out, in thinking it over afterwards, how it was that they began: all she remembers is, that they were running hand in hand, and the Queen went so fast that it was all she could do to keep up with her: and still the Queen kept crying 'Faster! Faster!' but Alice felt she could not go faster, though she had not breath left to say so. The most curious part of the thing was, that the trees and the other things round them never changed their places at all: however fast they went, they never seemed to pass anything. 'I wonder if all the things move along with us?' thought poor puzzled Alice. And the Queen seemed to guess her thoughts, for she cried, 'Faster! Don't try to talk!' Eventually, the Queen stops running and props Alice up against a tree, telling her to rest. Alice looked round her in great surprise. 'Why, I do believe we've been under this tree the whole time! Everything's just as it was!'

'Of course it is,' said the Queen, 'what would you have it?'

'Well, in our country,' said Alice, still panting a little, 'you'd generally get to somewhere else — if you ran very fast for a long time, as we've been doing.'

'A slow sort of country!' said the Queen. 'Now, here, you see, it takes all the running you can do, to keep in the same place.'

If you want to get somewhere else, you must run at least twice as fast as that!'

Smarter, Not Harder

The Red Queen Effect means that staying in the same place is falling behind. Surviving another day means we have to co-evolve with the systems we interact with.

If all animals evolved at the same rate, there would be no change in the relative interactions between species. However, not all animals evolve at the same rate. As Darwin observed, some are more “responsive to change” than others.

It is not the strongest of the species that survives, nor the most intelligent, but the one most responsive to change.

Charles Darwin

Species that are more responsive to change can gain a relative advantage over the ones they compete with and increase the odds of survival. In the short run, these small gains don't make much of a difference, but as generations pass the advantages compound. Everyone from Entrepreneurs and Fortune 500 CEOs to best-selling authors and middle managers are embedded with their own Red Queen. Rather than run harder, wouldn't it be nice to run smarter?

Examples of the Red Queen Effect

In *Deep Simplicity*, John Gribbon describes the red queen principle with frogs.

There are lots of ways in which the frogs, who want to eat flies, and the flies, who want to avoid being eaten, interact. Frogs might evolve longer tongues, for fly-catching purposes; flies might evolve faster flight, to escape. Flies might evolve an unpleasant taste, or even

excrete poisons that damage the frogs, and so on. We'll pick one possibility. If a frog has a particularly sticky tongue, it will find it easier to catch flies. But if flies have particularly slippery bodies, they will find it easier to escape, even if the tongue touches them. Imagine a stable situation in which a certain number of frogs live on a pond and eat a certain proportion of the flies around them each year.

Because of a mutation a frog develops an extra sticky tongue. It will do well, compared with other frogs, and genes for extra sticky tongues will spread through the frog population. At first, a larger proportion of flies gets eaten. But the ones who don't get eaten will be the more slippery ones, so genes for extra slipperiness will spread through the fly population. After a while, there will be the same number of frogs on the pond as before, and the same proportion of flies will be eaten each year. It looks as if nothing has changed – but the frogs have got stickier tongues, and the flies have got more slippery bodies.

Drugs and disease also represent an “arms-race.”

Siddhartha Mukherjee, in his Pulitzer-prize-winning book The Emperor of All Maladies, describes the red queen in the context of drugs and cancer.

In August 2000, Jerry Mayfield, a forty-one-year-old Louisiana policeman diagnosed with CML, began treatment with Gleevec. Mayfield's cancer responded briskly at first. The fraction of leukemic cells in his bone marrow dropped over six months. His blood count normalized and his symptoms improved; he felt rejuvenated—“like a new man [on] a wonderful drug.” But the response was short-lived. In the winter of 2003, Mayfield's CML stopped responding. Moshe Talpaz, the oncologist treating Mayfield in Houston, increased the dose of Gleevec, then increased it again, hoping to outpace the leukemia. But by October of that year, there was no response. Leukemia cells had fully recolonized his bone marrow and blood and invaded his spleen. Mayfield's cancer had become resistant to targeted therapy...

*... Even targeted therapy, then, was a cat-and-mouse game. One could direct endless arrows at the Achilles' heel of cancer, but the disease might simply shift its foot, switching one vulnerability for another. We were locked in a perpetual battle with a volatile combatant. When CML cells kicked Gleevec away, only a different molecular variant would drive them down, and when they outgrew that drug, then we would need the next-generation drug. If the vigilance was dropped, even for a moment, then the weight of the battle would shift. In Lewis Carroll's *Through the Looking-Glass*, the Red Queen tells Alice that the world keeps shifting so quickly under her feet that she has to keep running just to keep her position. This is our predicament with cancer: we are forced to keep running merely to keep still.*

This doesn't only happen in nature, there are many business examples as well.

In describing the capital investment needed to maintain a relative placement in the textile industry, Warren Buffett wrote:

Over the years, we had the option of making large capital expenditures in the textile operation that would have allowed us to somewhat reduce variable costs. Each proposal to do so looked like an immediate winner. Measured by standard return-on-investment tests, in fact, these proposals usually promised greater economic benefits than would have resulted from comparable expenditures in our highly-profitable candy and newspaper businesses.

But the promised benefits from these textile investments were illusory. Many of our competitors, both domestic and foreign, were stepping up to the same kind of expenditures and, once enough companies did so, their reduced costs became the baseline for reduced prices industrywide. Viewed individually, each company's capital investment decision appeared cost-effective and rational; viewed collectively, the decisions neutralized each other and were irrational (just as happens when each person watching a parade decides he can see a little better if he stands on tiptoes). After each round of investment, all the players had more money in the game and returns remained anemic.

In other words, more and more money is needed just to maintain your relative position in the industry and stay in the game. This situation plays out over and over again and brings with it many ripple effects. For example, the company distracted by maintaining a relative position in a poor industry places resources in a position almost assured to get a poor return on capital.

Inflation also causes a Red Queen Effect, here's Buffett Again:

Unfortunately, earnings reported in corporate financial statements are no longer the dominant variable that determines whether there are any real earnings for you, the owner. For only gains in purchasing power represent real earnings on investment. If you (a) forego ten hamburgers to purchase an investment; (b) receive dividends which, after tax, buy two hamburgers; and (c) receive, upon sale of your holdings, after-tax proceeds that will buy eight hamburgers, then (d) you have had no real income from your investment, no matter how much it appreciated in dollars. You may feel richer, but you won't eat richer. High rates of inflation create a tax on capital that makes much corporate investment unwise—at least if measured by the criterion of a positive real investment return to owners. This "hurdle rate" the return on equity that must be achieved by a corporation in order to produce any real return for its individual owners—has increased dramatically in recent years. The average tax-paying investor is now running up a down escalator whose pace has accelerated to the point where his upward progress is nil.

37. Mental Model: Game Theory

From Game Theory, by Morton Davis:

The theory of games is a theory of decision making. It considers how one should make decisions and to a lesser extent, how one does make them. You make a number of decisions every day. Some involve deep thought, while others are almost automatic. Your decisions are linked to your goals—if you know the consequences of each of your options, the solution is easy. Decide where you want to be and choose the path that takes you there. When you enter an elevator with a particular floor in mind (your goal), you push the button (one of your choices) that corresponds to your floor. Building a bridge involves more complex decisions but, to a competent engineer, is no different in principle. The engineer calculates the greatest load the bridge is expected to bear and designs a bridge to withstand it. When chance plays a role, however, decisions are harder to make. ... Game theory was designed as a decision-making tool to be used in more complex situations, situations in which chance and your choice are not the only factors operating. ... (Game theory problems) differ from the problems described earlier—building a bridge and installing telephones—in one essential respect: While decision makers are trying to manipulate their environment, their environment is trying to manipulate them. A store owner who lowers her price to gain a larger share of the market must know that her competitors will react in kind. ... Because everyone's strategy affects the outcome, a player must worry about what everyone else does and knows that everyone else is worrying about him or her.

What is a game? From Game Theory and Strategy:

Game theory is the logical analysis of situations of conflict and cooperation. More specifically, a game is defined to be any situation in which:

- 1. There are at least two players. A player may be an individual, but it may also be a more general entity like a company, a nation, or even a biological species.*
- 2. Each player has a number of possible strategies, courses of action which he or she may choose to follow.*
- 3. The strategies chosen by each player determine the outcome of the game.*
- 4. Associated to each possible outcome of the game is a collection of numerical payoffs, one to each player. These payoffs represent the value of the outcome to the different players.*

...Game theory is the study of how players should rationally play games. Each player would like the game to end in an outcome which gives him as large a payoff as possible.

From Greg Mankiw's Economics textbook:

Game theory is the study of how people behave in strategic situations. By 'strategic' we mean a situation in which each person, when deciding what actions to take, must consider how others might respond to that action. Because the number of firms in an oligopolistic market is small, each firm must act strategically. Each firm knows that its profit depends not only on how much it produces but also on how much the other firms produce. In making its production decision, each firm in an oligopoly should consider how its decision might affect the production decisions of all other firms.

Game theory is not necessary for understanding competitive or monopoly markets. In a competitive market, each firm is so small compared to the market that strategic interactions with other firms are not important. In a monopolized market, strategic interactions are absent because the market has only one firm. But, as we will see, game theory is quite useful for understanding the behavior of oligopolies.

A particularly important 'game' is called the prisoners' dilemma.

Markets with only a few sellers

Because an oligopolistic market has only a small group of sellers, a key feature of oligopoly is the tension between cooperation and self-interest. The oligopolists are best off when they cooperate and act like a monopolist – producing a small quantity of output and charging a price above marginal cost. Yet because each oligopolist cares only about its own profit, there are powerful incentives at work that hinder a group of firms from maintaining the cooperative outcome.

Avinash Dixit and Barry Nalebuff, in their book “Thinking Strategically” offer:

Everyone’s best choice depends on what others are going to do, whether it’s going to war or maneuvering in a traffic jam.

These situations, in which people’s choices depend on the behavior or the choices of other people, are the ones that usually don’t permit any simple summation. Rather we have to look at the system of interaction.

Michael J. Mauboussin relates game theory to firm interaction

How a firm interacts with other firms plays an important role in shaping sustainable value creation. Here we not only consider how many companies interact with their competitors, but how companies can co-evolve.

Game Theory is one of the best tools to understand interaction. Game Theory forces managers to put themselves in the shoes of other players rather than viewing games solely from their own perspective.

The classic two-player example of game theory is the prisoners’ dilemma.

38. The Principle of Incomplete Knowledge

“All models are wrong, but some are useful”

— George Box

If you think of the complicated world we live in you quickly realize that we need to sort the inessential from the essential and then reduce complexity into something simpler. In the same way the map is not the territory, knowledge is only but a subset of what it represents. In why knowledge is incomplete, the authors elaborate on these ideas:

This principle can be deduced from a lot of other, more specific principles: Heisenberg's uncertainty principle, implying that the information a control system can get is necessarily incomplete; the relativistic principle of the finiteness of the speed of light, implying that the moment information arrives, it is already obsolete to some extent; the principle of bounded rationality, stating that a decision-maker in a real-world situation will never have all information necessary for making an optimal decision; the principle of the partiality of self-reference, a generalization of Gödel's incompleteness theorem, implying that a system cannot represent itself completely, and hence cannot have complete knowledge of how its own actions may feed back into the perturbations. As a more general argument, one might note that models must be simpler than the phenomena they are supposed to model. Otherwise, variation and selection processes would take as much time in the model as in the real world, and no anticipation would be possible, precluding any control. Finally, models are constructed by blind variation processes, and, hence, cannot be expected to reach any form of complete representation of an infinitely complex environment.

39. Insensitivity To Base Rates: An Introduction

In statistics, a base rate refers to the percentage of a population (e.g. grasshoppers, people who live in New York, newborn babies) which have a characteristic. Given a random individual and no additional information, the base rate tells us the likelihood of them exhibiting that characteristic. For instance, around 10% of people are left-handed. If you selected a random person and had no information related to their handedness, you could safely guess there to be a 1 in 10 chance of them being left-handed.

When we make estimations, we often fail to consider the influence of base rates. This is a common psychological bias and is related to the representativeness heuristic.

From Smart Choices: A Practical Guide to Making Better Decisions:

Donald Jones is either a librarian or a salesman. His personality can best be described as retiring. What are the odds that he is a librarian?

When we use this little problem in seminars, the typical response goes something like this: "Oh, it's pretty clear that he's a librarian. It's much more likely that a librarian will be retiring; salesmen usually have outgoing personalities. The odds that he's a librarian must be at least 90 percent." Sounds good, but it's totally wrong.

The trouble with this logic is that it neglects to consider that there are far more salesmen than male librarians. In fact, in the United States, salesmen outnumber male librarians 100 to 1. Before you even considered the fact that Donald Jones is "retiring," therefore, you should have assigned only a 1 percent chance that Jones is a librarian. That is the base rate.

Now, consider the characteristic "retiring." Suppose half of all male librarians are retiring, whereas only 5 percent of salesmen are. That works out to 10 retiring salesmen for every retiring librarian — making the odds that Jones is a librarian closer to 10 percent than to 90 percent. Ignoring the base rate can lead you wildly astray.

* * *

Charlie Munger, instructs us how to think about base rates with an example of an employee who got caught for stealing, claiming she's never done it before and will never do it again:

You find an isolated example of a little old lady in the See's Candy Company, one of our subsidiaries, getting into the till. And what does she say? "I never did it before, I'll never do it again. This is going to ruin my life. Please help me." And you know her children and her friends, and she'd been around 30 years and standing behind the candy counter with swollen ankles. When you're an old lady it isn't that glorious a life. And you're rich and powerful and there she is: "I never did it before, I'll never do it again." Well how likely is it that she never did it before? If you're going to catch 10 embezzlements a year, what are the chances that any one of them — applying what Tversky and Kahneman called base rate information — will be somebody who only did it this once? And the people who have done it before and are going to do it again, what are they all going to say? Well in the history of the See's Candy Company they always say, "I never did it before, and I'm never going to do it again." And we cashier them. It would be evil not to, because terrible behavior spreads (Greshams law).

* * *

Max Bazerman, in Judgment in Managerial Decision Making, writes:

(Our tendency to ignore base rates) is even stronger when the specific information is vivid and compelling, as Kahneman and Tversky illustrated in one study from 1972. Participants were given a brief description of a person who enjoyed puzzles and was both mathematically inclined and introverted. Some participants were told that this description was selected from a set of seventy engineers and thirty lawyers. Others were told that the description came from a list of thirty engineers and seventy lawyers. Next, participants were asked to estimate the probability that the person described was an engineer. Even

though people admitted that the brief description did not offer a foolproof means of distinguishing lawyers from engineers, most tended to believe the description was of an engineer. Their assessments were relatively impervious to differences in base rates of engineers (70 percent versus 30 percent of the sample group.)

Participants do use base-rate data correctly when no other information is provided. In the absence of a personal description, people use the base rates sensibly and believe that a person picked at random from a group made up mostly of lawyers is most likely to be a lawyer. Thus, people understand the relevance of base-rate information, but tend to disregard such data when individuating data are also available.

Ignoring base rates has many unfortunate implications. ... Similarly, unnecessary emotional distress is caused in the divorce process because of the failure of couples to create prenuptial agreements that facilitate the peaceful resolution of a marriage. The suggestion of a prenuptial agreement is often viewed as a sign of bad faith. However, in far too many cases, the failure to create prenuptial agreements occurs when individuals approach marriage with the false belief that the high base rate for divorce does not apply to them.

* * *

Of course, this applies to investing as well. This conversation with Sanjay Bakshi speaks to this:

One of the great lessons from studying history is to do with “base rates”. “Base rate” is a technical term of describing odds in terms of prior probabilities. The base rate of having a drunken-driving accident is higher than those of having accidents in a sober state.

So, what’s the base rate of investing in IPOs? When you buy a stock in an IPO, and if you flip it, you make money if it’s a hot IPO. If it’s not a hot IPO, you lose money. But what’s the base rate – the averaged out experience – the prior probability of the activity of subscribing for IPOs – in the long run?

If you do that calculation, you’ll find that the base rate of IPO investing (in fact, it’s not even investing ... it’s speculating) sucks! [T]hat’s the case, not just in India, but in every market, in different time periods.

[...]

When you evaluate whether smoking is good for you or not, if you look at the average experience of 1,000 smokers and compare them with a 1,000 non-smokers, you’ll see what happens.

People don’t do that. They get influenced by individual stories like a smoker who lived till he was 95. Such a smoker will force many people to ignore base rates, and to focus on his story, to fool themselves into believing that smoking can’t be all that bad for them.

What is the base rate of investing in leveraged companies in bull markets?

[...]

This is what you learn by studying history. You know that the base rate of investing in an airline business sucks. There’s this famous joke about how to become a millionaire. You start with a billion, and then you buy an airline. That applies very well in this business. It applies in so many other businesses.

Take the paper industry as an example. Averaged out returns on capital for paper industry are bad for pretty good reasons. You are selling a commodity. It’s an extremely capital intensive business. There’s a lot of over-capacity. And if you understand microeconomics, you really are a price taker. There’s no pricing power for you. Extreme competition in such an environment is going to cause your returns on capital to be below what you would want to have.

It’s not hard to figure this out (although I took a while to figure it out myself). Look at the track record of paper companies around the world, and the airline companies around the world, or the IPOs around the world, or the textile companies around the world. Sure, there’ll be exceptions. But we need to focus on the average experience and not the

exceptional ones. The metaphor I like to use here is that of a pond. You are the fisherman. If you want to catch a lot of fish, then you must go to a pond where there's a lot of fish. You don't want to go to fish in a pond where there's very little fish. You may be a great fisherman, but unless you go to a pond where there's a lot of fish, you are not going to find a lot of fish.

[...]

So one of the great lessons from studying history is to see what has really worked well and what has turned out to be a disaster – and to learn from both.

40. Five Rules to help you Learn to Love Volatility

Nassim Taleb's book Antifragile: Things That Gain from Disorder is having a profound impact on how I see the world.

In this adapted piece from Antifragile, which appeared in the Wall Street Journal, Taleb offers five policy rules that can help us establish antifragility as a principle of our socioeconomic life.

Rule 1: Think of the economy as being more like a cat than a washing machine.

We are victims of the post-Enlightenment view that the world functions like a sophisticated machine, to be understood like a textbook engineering problem and run by wonks. In other words, like a home appliance, not like the human body. If this were so, our institutions would have no self-healing properties and would need someone to run and micromanage them, to protect their safety, because they cannot survive on their own.

By contrast, natural or organic systems are antifragile: They need some dose of disorder in order to develop. Deprive your bones of stress and they become brittle. This denial of the antifragility of living or complex systems is the costliest mistake that we have made in modern times. Stifling natural fluctuations masks real problems, causing the explosions to be both delayed and more intense when they do take place. As with the flammable material accumulating on the forest floor in the absence of forest fires, problems hide in the absence of stressors, and the resulting cumulative harm can take on tragic proportions.

And yet our economic policy makers have often aimed for maximum stability, even for eradicating the business cycle. "No more boom and bust," as voiced by the U.K. Labor leader Gordon Brown, was the policy pursued by Alan Greenspan in order to "smooth" things out, thus micromanaging us into the current chaos. Mr. Greenspan kept trying to iron out economic fluctuations by injecting cheap money into the system, which eventually led to monstrous hidden leverage and real-estate bubbles. On this front there is now at least a glimmer of hope, in the U.K. rather than the U.S., alas: Mervyn King, governor of the Bank of England, has advocated the idea that central banks should intervene only when an economy is truly sick and should otherwise defer action.

Promoting antifragility doesn't mean that government institutions should avoid intervention altogether. In fact, a key problem with overzealous intervention is that, by depleting resources, it often results in a failure to intervene in more urgent situations, like natural disasters. So in complex systems, we should limit government (and other) interventions to important matters: The state should be there for emergency-room surgery, not nanny-style maintenance and overmedication of the patient—and it should get better at the former.

In social policy, when we provide a safety net, it should be designed to help people take more entrepreneurial risks, not to turn them into dependents. This doesn't mean that we should be callous to the underprivileged. In the long run, bailing out people is less harmful to the system than bailing out firms; we should have policies now that minimize the possibility of being forced to bail out firms in the future, with the moral hazard this entails.

Rule 2: Favor businesses that benefit from their own mistakes, not those whose mistakes percolate into the system.

Some businesses and political systems respond to stress better than others. The airline industry is set up in such a way as to make travel safer after every plane crash. A tragedy leads to the thorough examination and elimination of the cause of the problem. The same thing happens in the restaurant industry, where the quality of your next meal depends on the failure rate in the business—what kills some makes others stronger. Without the high failure rate in the restaurant business, you would be eating Soviet-style cafeteria food for your next meal out.

These industries are antifragile: The collective enterprise benefits from the fragility of the individual components, so nothing fails in vain. These businesses have properties similar to evolution in the natural world, with a well-functioning mechanism to benefit from evolutionary pressures, one error at a time.

By contrast, every bank failure weakens the financial system, which in its current form is irremediably fragile: Errors end up becoming large and threatening. A reformed financial system would eliminate this domino effect, allowing no systemic risk from individual failures. A good starting point would be reducing the amount of debt and leverage in the economy and turning to equity financing. A firm with highly leveraged debt has no room for error; it has to be extremely good at predicting future revenues (and black swans). And when one leveraged firm fails to meet its obligations, other borrowers who need to renew their loans suffer as the chastened lenders lose their appetite to extend credit. So debt tends to make failures spread through the system.

A firm with equity financing can survive drops in income, however. Consider the abrupt deflation of the technology bubble during 2000. Because technology firms were relying on equity rather than debt, their failures didn't ripple out into the wider economy. Indeed, their failures helped to strengthen the technology sector.

Rule 3: Small is beautiful, but it is also efficient.

Experts in business and government are always talking about economies of scale. They say that increasing the size of projects and institutions brings costs savings. But the "efficient," when too large, isn't so efficient. Size produces visible benefits but also hidden risks; it increases exposure to the probability of large losses. Projects of \$100 million seem rational, but they tend to have much higher percentage overruns than projects of, say, \$10 million. Great size in itself, when it exceeds a certain threshold, produces fragility and can eradicate all the gains from economies of scale. To see how large things can be fragile, consider the difference between an elephant and a mouse: The former breaks a leg at the slightest fall, while the latter is unharmed by a drop several multiples of its height. This explains why we have so many more mice than elephants.

So we need to distribute decisions and projects across as many units as possible, which reinforces the system by spreading errors across a wider range of sources. In fact, I have argued that government decentralization would help to lower public deficits. A large part of these deficits comes from underestimating the costs of projects, and such underestimates are more severe in large, top-down governments. Compare the success of the bottom-up mechanism of canton-based decision making in Switzerland to the failures of authoritarian regimes in Soviet Russia and Baathist Iraq and Syria.

Rule 4: Trial and error beats academic knowledge.

Things that are antifragile love randomness and uncertainty, which also means—crucially—that they can learn from errors. Tinkering by trial and error has traditionally played a larger role than directed science in Western invention and innovation. Indeed, advances in theoretical science have most often emerged from technological development, which is closely tied to entrepreneurship. Just think of the number of famous college dropouts in the computer industry.

But I don't mean just any version of trial and error. There is a crucial requirement to achieve antifragility: The potential cost of errors needs to remain small; the potential gain should be large. It is the asymmetry between upside and downside that allows antifragile tinkering to benefit from disorder and uncertainty.

Perhaps because of the success of the Manhattan Project and the space program, we greatly overestimate the influence and importance of researchers and academics in technological advancement. These people write books and papers; tinkerers and engineers don't, and are thus less visible. Consider Britain, whose historic rise during the Industrial Revolution came from tinkerers who gave us innovations like iron making, the steam engine and textile manufacturing. The great names of the golden years of English

science were hobbyists, not academics: Charles Darwin, Henry Cavendish, William Parsons, the Rev. Thomas Bayes. Britain saw its decline when it switched to the model of bureaucracy-driven science.

America has emulated this earlier model, in the invention of everything from cybernetics to the pricing formulas for derivatives. They were developed by practitioners in trial-and-error mode, drawing continuous feedback from reality. To promote antifragility, we must recognize that there is an inverse relationship between the amount of formal education that a culture supports and its volume of trial-and-error by tinkering. Innovation doesn't require theoretical instruction, what I like to compare to "lecturing birds on how to fly."

Rule 5: Decision makers must have skin in the game.

At no time in the history of humankind have more positions of power been assigned to people who don't take personal risks. But the idea of incentive in capitalism demands some comparable form of disincentive. In the business world, the solution is simple: Bonuses that go to managers whose firms subsequently fail should be clawed back, and there should be additional financial penalties for those who hide risks under the rug. This has an excellent precedent in the practices of the ancients. The Romans forced engineers to sleep under a bridge once it was completed.

Because our current system is so complex, it lacks elementary clarity: No regulator will know more about the hidden risks of an enterprise than the engineer who can hide exposures to rare events and be unharmed by their consequences. This rule would have saved us from the banking crisis, when bankers who loaded their balance sheets with exposures to small probability events collected bonuses during the quiet years and then transferred the harm to the taxpayer, keeping their own compensation.

In these five rules, I have sketched out only a few of the more obvious policy conclusions that we might draw from a proper appreciation of antifragility. But the significance of antifragility runs deeper. It is not just a useful heuristic for socioeconomic matters but a crucial property of life in general. Things that are antifragile only grow and improve under adversity. This dynamic can be seen not just in economic life but in the evolution of all things, from cuisine, urbanization and legal systems to our own existence as a species on this planet.

We all know that the stressors of exercise are necessary for good health, but people don't translate this insight into other domains of physical and mental well-being. We also benefit, it turns out, from occasional and intermittent hunger, short-term protein deprivation, physical discomfort and exposure to extreme cold or heat. Newspapers discuss post-traumatic stress disorder, but nobody seems to account for post-traumatic growth. Walking on smooth surfaces with "comfortable" shoes injures our feet and back musculature: We need variations in terrain.

Modernity has been obsessed with comfort and cosmetic stability, but by making ourselves too comfortable and eliminating all volatility from our lives, we do to our bodies and souls what Mr. Greenspan did to the U.S. economy: We make them fragile. We must instead learn to gain from disorder.

41. Erik Hollnagel: The Search For Causes

A great passage from Erik Hollnagel's Barriers And Accident Prevention on the search for causes:

Whenever an accident happens there is a natural concern to find out in detail exactly what happened and to determine the causes of it. Indeed, whenever the result of an action or event falls significantly short of what was expected, or whenever something unexpected happens, people try to find an explanation for it. This trait of human nature is so strong that we try to find causes even when they do not exist, such as in the case of misleading or spurious correlations. For a number of reasons humans seem to be extremely reluctant to accept that something can happen by chance. One very good reason is that we have created a way of living that depends heavily on the use of technology, and that technological systems are built to function in a deterministic, hence reliable manner. If therefore something fails, we are fully justified in trying to find the reason for it. A second reason is that our whole understanding of the world is based on the assumption of specific relations between causes and effects, as amply illustrated by the Laws of Physics. (Even in quantum physics there are assumptions of more fundamental relations that are deterministic.) A third reason is that most humans find it very uncomfortable when they do not know what to expect, i.e., when things happen in an unpredictable manner. This creates a sense of being out of control, something that is never desirable since – from an evolutionary perspective – it means that the chances of survival are reduced.

This was described by Friedrich Nietzsche when he wrote:

[T]o trace something unknown back to something known is alleviating, soothing, gratifying and gives moreover a feeling of power. Danger, disquiet, anxiety attend the unknown – the first instinct is to eliminate these distressing states. First principle: any explanation is better than none ... The cause-creating drive is thus conditioned and excited by the feeling of fear.

Hollnagel, continues:

A well-known example of this is provided by the phenomenon called the gambler's fallacy. The name refers to the fact that gamblers often seem to believe that a long row of events of one type increases the probability of the complementary event. Thus if a series of 'red' events occur on a roulette wheel, the gambler's fallacy lead people to believe that the probability of 'black' increases. ... Rather than accepting that the underlying mechanism may be random people invent all kinds of explanations to reduce the uncertainty of future events.

42. Mental Model: Equilibrium

There are many ways in which you can visualize the concept of equilibrium, but one of the simplest comes from Boombustology where a ball sits on a simple curved shape.

Source: Boombustology

A situation in which equilibrium is possible is one in which over time, if left to its own devices, the ball will find one unique location. Overshooting and undershooting this unique location is self-correcting. A situation of disequilibrium, however, is one in which the ball is unable to find a unique location. A ball in such a state does not generate self-correcting moves that dampen its moves toward a theoretical “equilibrium” or resting spot; rather, disequilibrium generates motion that is self-reinforcing and accelerates the ball’s move away from any stable state.

Let’s take a step back and thank Netwon.

In *Principia*, he describes his three laws of motion. Using planets, these laws allowed Newton to demonstrate how gravitational forces act between two bodies. He showed that the force of the sun’s gravity (pulling planets toward the sun) is offset by their forward velocity. These two forces, equal in nature, create a state of equilibrium.

Equilibrium is a balance between one or more opposing forces. As you can imagine, different types of equilibrium exist. Static equilibrium is when a system is at rest. Dynamic equilibrium is when two or more forces are equally matched. Robert Hagstorm, in the Last Liberal Art, helps illustrate the difference between the two:

A scale that is equally weighted on both sides is an example of static equilibrium. Fill a bathtub full of water and then turn off the faucet and you will observe static equilibrium. But if you unplug the drain and then turn on the faucet so the level of the bathtub does not change, you are witnessing dynamic equilibrium. Another example is the human body. It remains in dynamic equilibrium so long as the heat loss from cooling remains in balance with the consumption of sugars.

Supply and Demand + Equilibrium

The rule of supply and demand, from economics, is also an example of the law of equilibrium.

In 1997 Warren Buffett, through his company Berkshire Hathaway, purchased 11.2 million ounces of silver-based on his understanding of equilibrium. In his annual letter for that year, he succinctly sums up the investment:

In recent years, bullion inventories have fallen materially, and last summer Charlie (Munger) and I concluded that a higher price would be needed to establish equilibrium between supply and demand.

Too little supply and equilibrium is out of balance. Buffett (correctly) bet that the only way to bring the market back into a state of equilibrium was rising prices. Demand, the balancing force to supply, can also result in successful investments.

In his 2011 shareholder letter, Buffett again illustrates the concept of equilibrium through supply and demand.

Today the world’s gold stock is about 170,000 metric tons. If all of this gold were melded together, it would form a cube of about 68 feet per side. (Picture it fitting comfortably within a baseball infield.) At \$1,750 per ounce – gold’s price as I write this – its value would be

\$9.6 trillion. Call this cube pile A. Let's now create a pile B costing an equal amount. For that, we could buy all U.S. cropland (400 million acres with output of about \$200 billion annually), plus 16 Exxon Mobils (the world's most profitable company, one earning more than \$40 billion annually). After these purchases, we would have about \$1 trillion left over for walking-around money (no sense feeling strapped after this buying binge). Can you imagine an investor with \$9.6 trillion selecting pile A over pile B?

Beyond the staggering valuation given the existing stock of gold, current prices make today's annual production of gold command about \$160 billion. Buyers – whether jewelry and industrial users, frightened individuals, or speculators – must continually absorb this additional supply to merely maintain an equilibrium at present prices.

A century from now the 400 million acres of farmland will have produced staggering amounts of corn, wheat, cotton, and other crops – and will continue to produce that valuable bounty, whatever the currency may be. Exxon Mobil will probably have delivered trillions of dollars in dividends to its owners and will also hold assets worth many more trillions (and, remember, you get 16 Exxons). The 170,000 tons of gold will be unchanged in size and still incapable of producing anything. You can fondle the cube, but it will not respond.

Admittedly, when people a century from now are fearful, it's likely many will still rush to gold. I'm confident, however, that the \$9.6 trillion current valuation of pile A will compound over the century at a rate far inferior to that achieved by pile B.

In Boombustology, Mansharamani writes:

Inherent in most equilibrium-oriented approaches is a belief that higher prices generate new supply that tends to push prices down. Likewise, it is believed that lower prices generate new demand that tends to push prices up. In this way, deviations from an appropriate price level are self-correcting.

A grasp of supply and demand can help us make better investment decisions. The producers of undifferentiated goods, (e.g., an aluminium can), are (usually) poor investments because the only way they will make adequate returns is under conditions of tight supply. If any excess capacity exists in the industry, prices will trend down towards the cost of producing. In this case, owners are left with unsatisfactory returns on their investment.

The only real winners are the low cost producers. As prices trend down only they can maintain full production whereas high cost competitors must cut production, which starts reducing supply and moves the industry towards equilibrium. When business picks up again, as it inevitably does, the production that was once shuttled comes back online. Only low-cost producers can operate throughout the cycle. Opportunities to profit from equilibrium exist when demand outstrips capacity, which usually results from (1) a positive change in demand or (2) a negative change in supply.

While seductively simple, this model of equilibrium in financial markets is somewhat incomplete. We must consider reflexivity.

George Soros writes, "Reflexivity is, in effect, a two-way feedback mechanism in which reality helps shape the participants' thinking and the participants' thinking helps shape reality in an unending process in which thinking and reality may come to approach each other but can never become identical."

The implications of reflexivity on financial markets are quite profound, particularly with regard to the existence of an equilibrium price. Soros describes these implications in his own words succinctly:

Instead of a tendency towards some kind of theoretical equilibrium, the participants' views and actual state of affairs enter into a process of dynamic disequilibrium, which may be self-reinforcing at first, moving both thinking and reality in a certain direction, but is bound to become unsustainable in the long run and engender a move in the opposite direction.

Soros' testimony in 1994 to the House Banking Committee summarizes his theory of reflexivity and how it manifests itself in financial markets:

I must state at the outset that I am in fundamental disagreement with the prevailing wisdom. The generally accepted theory is that markets tend towards equilibrium and on the whole discount the future correctly. I operate using a different theory, according to which financial markets cannot possibly discount the future correctly because they do not merely discount the future, they help to shape it. In certain circumstances, financial markets can affect the so-called fundamentals which they are supposed to reflect. When that happens, markets enter into a state of dynamic disequilibrium and behave quite differently than what would be considered normal by the theory of efficient markets. Such boom/bust sequences do not arise very often, but when they do, they can be very disruptive, precisely because they affect the fundamentals of the economy.

In Boombustology, Mansharamani writes:

... financial extremes are characterized by two primary components: a prevailing trend that exists in reality and a misconception relating to it. He often uses real estate as an example to illustrate this point. The prevailing trend in reality is that there is an increased willingness to lend and a corresponding rise in prices. The misconception relating to this trend is that the prices of real estate are independent of the willingness to lend. Further, as more banks become willing to lend, and the number of buyers therefore rises, the prices of real estate rise—thereby making the banks feel more secure (given higher collateral values) and driving more lending.

Feedback Loops and Equilibrium

In Universal Principles of Design, William Lidwell & co. write:

Every action creates an equal and opposite reaction. When reactions loop back to affect themselves, a feedback loop is created. All real-world systems are composed of many such interacting feedback loops — animals, machines, businesses, and ecosystems, to name a few. There are two types of feedback loops: positive and negative. Positive feedback amplifies system output, resulting in growth or decline. Negative feedback dampers output, stabilizes the system around an equilibrium point.

Positive feedback loops are effective for creating change, but generally result in negative consequences if not moderated by negative feedback loops. For example, in response to head and neck injuries in football in the late 1950s, designers created plastic football helmets with internal padding to replace leather helmets. The helmets provided more protection, but induced players to take increasingly greater risks when tackling. More head and neck injuries occurred (after the introduction of plastic helmets) than before. By concentrating on the problem in isolation (e.g., not considering changes in player behavior) designers inadvertently created a positive feedback loop in which players used their head and neck in increasingly risky ways. This resulted in more injuries which resulted in additional redesigns that made the helmet shells harder and more padded and so on.

Negative feedback loops are effective for resisting change. For example, the Segway Human Transporter uses negative feedback loops to maintain equilibrium. As a rider leans forward or backward, the Segway accelerates or decelerates to keep the system in equilibrium. To achieve this smoothly, the Segway makes hundreds of adjustments every second. Given the high adjustment rate, the oscillations around the point of equilibrium are so small as to not be detectable. However, if fewer adjustments were made per second, the oscillations would increase in size and the ride would become increasingly jerky.

Diseases and Equilibrium

Malcolm Gladwell illustrates this in The Tipping Point with a hypothetical outbreak of the flu.

Suppose, for example, that one summer 1,000 tourists come to Manhattan from Canada carrying an untreatable strain of twenty-four-hour virus. This strain of flu has a 2 percent infection rate, which is to say that one out of every 50 people who come into close contact

with someone carrying it catches the bug himself. Let's say that 50 is also exactly the number of people the average Manhattanite — in the course of riding the subways and mingling with colleagues at work — comes into contact with every day. What we have, then, is a disease in equilibrium. Those 1,000 Canadian tourists pass on the virus to 1,000 new people on the day they arrive. And the next day those 1,000 newly infected people pass on the virus to another 1,000 people, just as the original 1,000 tourists who started the epidemic are returning to health. With those getting sick and those getting well so perfectly in balance, the flu chugs along at a steady but unspectacular clip through the test of summer and fall.

But then comes the Christmas season. The subways and buses get more crowded with tourists and shoppers, and instead of running into an even 50 people a day, the average Manhattanite now has close contact with, say, 55 people a day. All of a sudden, the equilibrium is disrupted. The 1,000 flu carriers now run into 55,000 people a day and at a 2 percent infection rate, that translates into 1,100 cases the following day. Those 1,100, in turn, are now passing on their virus to 55,000 people as well, so that by day three there are 1,210 Manhattanites with the flu and by day four 1,331 and by the end of the week there are nearly 2,000, and so on up, in an exponential spiral until Manhattan has a full-blow flu epidemic on its hands by Christmas Day. That moment when the average flu carrier went from running into 50 people a day to running into 55 was the Tipping point. It was the point at which an ordinary and stable phenomenon — a low-level flu outbreak — turned into a public health crisis. If you were to draw a graph of the progress of the Canadian flu epidemic, the Tipping point would be the point on the graph where it suddenly turned upward.

43. Competitive Strategy

An organization's core capabilities are those activities that, when performed at the highest level, enable the organization to bring its where-to-play and how-to-win choices to life. They are best understood as operating as a system of reinforcing activities— a concept first articulated by Harvard Business School's Michael Porter. Porter noted that powerful and sustainable competitive advantage is unlikely to arise from any one capability (e.g., having the best sales force in the industry or the best technology in the industry), but rather from a set of capabilities that both fit with one another (i.e., that don't conflict with one another) and actually reinforce one another (i.e., that make each other stronger than they would be alone).

For Porter, a company's "strategic position is contained in a set of tailored activities designed to deliver it." He calls the visual depiction of this set of activities an activity system. Since "competitive strategy is about being different ... [and] means deliberately choosing a different set of activities to deliver unique value," an activity system must also be distinctive from the activity systems of competitors. In his landmark 1996 article "What Is Strategy?," Porter illustrated his theory with examples from Southwest Airlines, Progressive Insurance, and The Vanguard Group, articulating the way in which each organization made distinctive choices and tailored an activity system to deliver on those choices. The activity system is a visual representation of the firm's competitive advantage, capturing on a single page the core capabilities of the firm. Articulating a firm's core capabilities is a vital step in the strategy process. Identifying the capabilities required to deliver on the where-to-play and how-to-win choices crystallizes the area of focus and investment for the company. It enables a firm to continue to invest in its current capabilities, to build up others, and to reduce the investment in capabilities that are not essential to the strategy.

44. The Nature of Explanation

We unconsciously construct mental models of the world and these models help aid our thinking.

This idea is not new. In fact, in 1943 Kenneth Craik proposed that thinking is the manipulation of internal representations of the world in his book The Nature of Explanation.

“This deceptively simple notion,” argues Philip Johnson-Laird in Mental Models, “has rarely been taken sufficiently seriously by psychologists, particularly by those studying language and thought.”

They certainly argue that there are mental representations — images, or strings of symbols — and that information in them is processed by the mind; but they ignore a crucial issue: what it is that makes a mental entity a representation of something. In consequence, psychological theories of meaning almost invariably fail to deal satisfactorily with referential phenomena. A similar neglect of the subtleties of mental representation has led to psychological theories of reasoning that almost invariably assume, either explicitly or implicitly, the existence of a mental logic.

Explanation depends on understanding. If you don't understand something you cannot explain it. Although what is explanation? “It is easier to give criteria for what counts as understanding than to capture its essence — perhaps because it has no essence,” writes Johnson-Laird.

This will no doubt strike many of you as fuzzy. Justice Stewart found it impossible to formulate a test for obscenity but nevertheless asserted, “I know it when I see it,” so can we, in an inexact, yet useful way, when it comes to explanations.

Explanations certainly require knowledge and understanding. Johnson-Laird writes:

If you know what causes a phenomenon, what results from it, how to influence, control, initiate, or prevent it, how it relates to other states of affairs or how it resembles them, how to predict its onset and course, what its internal or underlying “structure” is, then to some extent you understand it.

The psychological core of understanding, I shall assume, consists in your having a “working model” of the phenomenon in your mind. If you understand inflation, a mathematical proof, the way a computer works, DNA or a divorce, then you have a mental representation that serves as a model of an entity in much the same way as, say, a clock functions as a model of the earth's rotation.

This is where Kenneth Craik comes into the picture. His 1943 book The Nature of Explanation was one of the first, if not the first, to propose that human beings think by manipulating internal representations of the world. This manipulation — or reasoning — involves three distinct processes:

1. A translation of some external process into an internal representation in terms of words, numbers, or other symbols.
2. The derivation of other symbols from them by some sort of inferential process.
3. A re-translation of these symbols into actions, or at least a recognition of the correspondence between these symbols and external events, as in realizing that a prediction is fulfilled.

In The Nature of Explanation Craik writes this beautiful passage:

One other point is clear; this process of reasoning has produced a final result similar to that which might have been reached by causing the actual physical processes to occur (e.g. building the bridge haphazard mid measuring its strength or compounding certain chemicals and seeing what happened); but it is also clear that this is not what has happened; the man's mind does not contain a material bridge or the required chemicals. Surely, however, this process of prediction is not unique to minds, though no doubt it is hard to imitate the flexibility and versatility of mental prediction. A calculating machine, an

anti-aircraft 'predictor', and Kelvin's tidal predictor all show the same ability. In all these latter cases, the physical process which it is desired to predict is imitated by some mechanical device or model which is cheaper, or quicker, or more convenient in operation. Here we have a very close parallel to our three stages of reasoning-the 'translation' of the external processes into their representatives (positions of gears, etc.) in the model; the arrival at other positions of gears, etc., by mechanical processes in the instrument; and finally, the retranslation of these into physical processes of the original type.

By a model we thus mean any physical or chemical system, which has a similar relation-structure to that of the process it imitates. By relation-structure I do not mean some obscure non-physical entity which attends the model, but the fact that it is a physical working model which works in the same way as the process it parallels, in the aspects under consideration at any moment. Thus, the model need not resemble the real object pictorially; Kelvin's tide predictor, which consists of a number of pulleys on levers, does not resemble a tide in appearance, but it works in the same way in certain essential respects-it combines oscillations of various frequencies so as to produce an oscillation which closely resembles in amplitude at each moment the variation in tide level at any place. ...

My hypothesis then is that thought models, or parallels, reality — that its essential feature is not 'the mind', 'the self', 'sense-data' nor propositions but symbolism, and that this symbolism is largely of the same kind as that which is familiar to us in mechanical devices which aid thought and calculation. ...

If the organism carries a 'small-scale model' of external reality and of its own possible actions within its head, it is able to try out various alternatives, conclude which is the best of them, react to future situations before they arise, utilize the knowledge of past events in dealing with the present and future, and in every way to react in a much fuller, safer, and more competent manner to the emergencies which face it. Most of the greatest advances of modern technology have been instruments, which extended the scope of our sense-organs, our brains or our limbs. Such are telescopes and microscopes, wireless, calculating machines, typewriters, motor cars, ships and aeroplanes. Is it not possible, therefore, that our brains themselves utilize comparable mechanisms to achieve the same ends and that these mechanisms can parallel phenomena in the external world as a calculating machine can parallel the development of strains in a bridge?

Small models of reality need neither be wholly accurate nor correspond completely with what they model to be useful. Your model of an iPhone may contain only the idea of a rectangle that serves multiple functions such as sending and receiving data, apps, displaying moving pictures with accompanying sound. Alternatively, it may consist of an understanding of the programming necessary to make the device work, the protocols, the physical limitations, and how the display actually functions, in which case you've eclipsed me. Your model may be deeper still, into the hardware and how it works, etc. A person who repairs iPhones is likely to have a more comprehensive model of them than someone who only operates one. The engineers at Apple are likely to have a richer model than most of us.

What must be questioned now is whether adding information increases the usefulness of the model. If I explain how operating systems and API's work, you will have a much richer model of an iPhone. For some of you that will mean a more useful model and for some it will not.

"Many of the models in people's minds are," Johnson-Laird writes, "little more than high-grade simulations, but they are none the less useful provided that the picture is accurate; all representations of physical phenomena necessarily contain an element of simulation." So the nature of an explanation is to understand something – to have a working model of it. All explanations are incomplete because at some point they all must take something for granted. When you explain something to another person, "what is conveyed is a blueprint for the construction of a working model."

Obviously, a satisfactory blueprint for one individual may be grossly inadequate for another, since any set of instructions demands the knowledge and ability to understand them. ... In most domains of expertise, there is a consensus about what counts as a satisfactory explanation — a consensus based on common knowledge and formulable in public criteria."

Still Curious? Try reading these three books in the following order: 1) The Nature of Explanation; 2) Mental Models; and 3) How We Reason.

45. Power Laws: How Nonlinear Relationships Amplify Results

“The greatest shortcoming of the human race is our inability to understand the exponential function.”

— Albert Allen Bartlett

Defining A Power Law

Consider a person who begins weightlifting for the first time.

During their initial sessions, they can lift only a small amount of weight. But as they invest more time, they find that for each training session, their strength increases a surprising amount.

For a while, they make huge improvements. Eventually, however, their progress slows down. At first, they could increase their strength by as much as 10% per session; now it takes months to improve by even 1%. Perhaps they resort to taking performance-enhancing drugs or training more often. Their motivation is sapped, and they find themselves getting injured, without any real change in the amount of weight they can lift. Now, let's imagine that our frustrated weightlifter decides to take up running instead. Something similar happens. While the first few runs are incredibly difficult, the person's endurance increases rapidly with the passing of each week, until it levels off and diminishing returns set in again.

Both of these situations are examples of *power laws* — a relationship between two things in which a change in one thing can lead to a large change in the other, regardless of the initial quantities. In both of our examples, a small investment of time at the beginning of the endeavor leads to a large increase in performance.

Power laws are interesting because they reveal surprising correlations between disparate factors. As a mental model, power laws are versatile, with numerous applications in different fields of knowledge.

If parts of this post look intimidating to non-mathematicians, bear with us. Understanding the math behind power laws is worthwhile to grasp their many applications. Invest a little time in reading this and reap the value — which is in itself an example of a power-law!

A power law is often represented by an equation with an exponent:

$$Y=MX^B$$

Each letter represents a number. Y is a function (the result); X is the variable (the thing you can change); B is the order of scaling (the exponent), and M is a constant (unchanging). If M is equal to 1, the equation is then $Y=X^B$. If $B=2$, the equation becomes $Y=X^2$ ($Y=X$ squared). If X is 1, Y is also 1. But if $X=2$, then $Y=4$; if $X=3$, then $Y=9$, and so on. A small change in the value of X leads to a proportionally large change in the value of Y.

$B=1$ is known as the linear scaling law.

To double a cake recipe, you need twice as much flour. To drive twice as far will take twice as long. (Unless you have kids, in which case you need to factor in bathroom breaks that seemingly have little to do with distance.) Linear relationships, in which twice-as-big requires twice-as-much, are simple and intuitive.

Nonlinear relationships are more complicated. In these cases, you don't need twice as much of the original value to get twice the increase in some measurable characteristic. For example, an animal that's twice our size requires only about 75% more food than we do. This means that on a per-unit-of-size basis, larger animals are more energy-efficient than smaller ones. As animals get bigger, the energy required to support each unit decreases. One of the characteristics of a complex system is that the behavior of the system differs from the simple addition of its parts. This characteristic is called emergent behavior. “In many instances,” write Geoffrey West in *Scale: The Universal Laws of Growth, Innovation, Sustainability, and the Pace of Life in Organisms, Cities, Economies, and Companies*, “the whole seems to take on a life of its own, almost dissociated from the specific characteristics of its individual building blocks.”

This collective outcome, in which a system manifests significantly different characteristics from those resulting from simply adding up all of the contributions of its individual constituent parts, is called an emergent behavior.

When we set out to understand a complex system, our intuition tells us to break it down into its component pieces. But that's *linear* thinking, and it explains why so much of our thinking about complexity falls short. Small changes in a complex system can cause sudden and large changes. Small changes cause cascades among the connected parts, like knocking over the first domino in a long row.

Let's return to the example of our hypothetical weightlifter-turned-runner. As they put in more time on the road, constraints will naturally arise on their progress.

Recall our exponential equation: $Y = MX^B$. Try applying it to the runner. (We're going to simplify running, but stick with it.)

Y is the distance the runner can run before becoming exhausted. That's what we're trying to calculate. M, the constant, represents their running ability: some combination of their natural endowment and their training history. (Think of it this way: Olympic champion Usain Bolt has a high M; film director Woody Allen has a low M.)

That leaves us with the final term: X^B . The variable X represents the thing we have control over: in this case, our training mileage. If B, the exponent, is between 0 and 1, then the relationship between X and Y— between training mileage and endurance — becomes progressively less proportional. All it takes is plugging in a few numbers to see the effect. Let's set M to 1 for the sake of simplicity. If $B = 0.5$ and $X = 4$, then $Y = 2$. Four miles on the road gives the athlete the ability to run two miles at a clip.

Increase X to 16, and Y increases only to 4. The runner has to put in four times the road mileage to merely double their running endurance.

Here's the kicker: With both running and weightlifting, as we increase X, *we're likely to see the exponent, B, decline!* Quadrupling our training mileage from 16 to 64 miles is unlikely to double our endurance again. It might take a 10x increase in mileage to do that.

Eventually, the ratio of training mileage to endurance will become nearly infinite.

We know this state, of course, as diminishing returns: the point where more input yields progressively less output. Not only is the relationship between training mileage and endurance not linear to begin with, but it also gets *less* linear as we increase our training.

And what about negative exponents?

It gets even more interesting. If $B = -0.5$ and $X = 4$, then $Y = 0.5$. Four miles on the road gets us a half-mile of endurance. If X is increased to 16, Y declines to 0.25. More training, *less* endurance! This is akin to someone putting in way too much mileage, way too soon: the training is less than useful as injuries pile up.

With negative numbers, the more X increases, the more Y *shrinks*. This relationship is known as an *inverse power law*. $B = -2$, for example, is known as the *inverse square law* and is an important equation in physics.

The relationship between gravity and distance follows an inverse power law. G is the gravitational constant; it's the constant in Newton's law of gravitation, relating gravity to the masses and separation of particles, equal to:

$$6.67 \times 10^{-11} \text{ N m}^2 \text{ kg}^{-2}$$

Any force radiating from a single point — including heat, light intensity, and magnetic and electrical forces — follows the inverse square law. At 1m away from a fire, 4 times as much heat is felt as at 2m, and so on.

Higher-Order Power Laws

When B is a positive integer (a whole number larger than zero), there are names for the power laws.

When B is equal to 1, we have a linear relationship, as we discussed above. This is also known as a first-order power law.

Things really get interesting after that.

When B is 2, we have a second-order power law. A great example of this is kinetic energy. Kinetic energy = $\frac{1}{2} mv^2$

When B is 3, we have a third-order power law. An example of this is the power converted from the wind into rotational energy.

Power Available = $\frac{1}{2} (\text{Air Density})(\pi r^2)(\text{Windspeed}^3)(\text{Power Coefficient})$

(There is a natural limit here. Albert Betz concluded in 1919 that wind turbines cannot convert more than 59.3% of the kinetic energy of the wind into mechanical energy. This number is called the Betz Limit and represents the power coefficient above.)[1]

The law of heat radiation is a fourth-order power law. Derived first by the Austrian physicist Josef Stefan in 1879 and separately by Austrian physicist Ludwig Boltzmann, the law works like this: the radiant heat energy emitted from a unit area in one second is equal to the constant of proportionality (the Stefan-Boltzmann constant) times the absolute temperature to the fourth power.[2]

There is only one power-law with a variable exponent, and it's considered to be one of the most powerful forces in the universe. It's also the most misunderstood. We call it compounding. The formula looks like this:

Future Value = (Present Value)(1+i)ⁿ

where i is the interest rate, and n is the number of years.

Unlike in the other equations, the relationship between X and Y is potentially limitless. As long as B is positive, Y will increase as X does.

Non-integer power laws (where B is a fraction, as with our running example above) are also of great use to physicists. Formulas in which B=0.5 are common.

Imagine a car driving at a certain speed. A non-integer power law applies. V is the speed of the car, P is the petrol burnt per second to reach that speed, and A is the air resistance. For the car to go twice as fast, it must use 4 times as much petrol, and to go 3 times as fast, it must use 9 times as much petrol. Air resistance increases as speed increases, and that is why faster cars use such ridiculous amounts of petrol. It might seem logical to think that a car going from 40 miles an hour to 50 miles an hour would use a quarter more fuel. That is incorrect, though, because the relationship between air resistance and speed is itself a power law.

Another instance of a power law is the area of a square. Double the length of two parallel sides and the area quadruples. Do the same for a 3D cube, and the area increases by a factor of eight. It doesn't matter if the length of the square went from 1cm to 2cm, or from 100m to 200m; the area still quadruples. We are all familiar with second-order (or square) power laws. This name comes from squares since the relationship between length and area reflects the way second-order power laws change a number. Third-order (or cubic) power laws are likewise named due to their relationship to cubes.

Using Power Laws in Our Lives

Now that we've gotten through the complicated part let's take a look at how power laws crop up in many fields of knowledge. Most careers involve an understanding of them, even if it might not be so obvious.

"What's the most powerful force in the universe? Compound interest. It builds on itself. Over time, a small amount of money becomes a large amount of money. Persistence is similar. A little bit improves performance, which encourages greater persistence, which improves persistence even more. And on and on it goes."

— Daniel H. Pink, The Adventures of Johnny Bunko

The Power Behind Compounding

Compounding is one of our most important mental models and is absolutely vital to understand for investing, personal development, learning, and other crucial areas of life. In economics, we calculate compound interest by using an equation with these variables: P is the original sum of money. P' is the resulting sum of money, r is the annual interest

rate, n is the compounding frequency, and t is the length of time. Using an equation, we can illustrate the power of compounding.

If a person deposits \$1000 in a bank for five years, at a quarterly interest rate of 4%, the equation becomes this:

Future Value = Present Value * $((1 + \text{Quarterly Interest Rate})^{\text{Number of Quarters}})$

This formula can be used to calculate how much money will be in the account after five years. The answer is \$2,220.20.

Compound interest is a power law because the relationship between the amount of time a sum of money is left in an account and the amount accumulated at the end is non-linear.

In *A Random Walk Down Wall Street*, Burton Malkiel gives the example of two brothers, William and James. Beginning at age 20 and stopping at age 40, William invests \$4,000 per year. Meanwhile, James invests the same amount per year between the ages of 40 and 65. By the time William is 65, he has invested less money than his brother but has allowed it to compound for 25 years. As a result, when both brothers retire, William has 600% more money than James — a gap of \$2 million. One of the smartest financial choices we can make is to start saving as early as possible: by harnessing power laws, we increase the exponent as much as possible.

Compound interest can help us achieve financial freedom and wealth, without the need for a large annual income. Members of the financial independence movement (such as the blogger Mr. Money Mustache) are living examples of how we can apply power laws to our lives.

As far back as the 1800s, Robert G. Ingersoll emphasized the importance of compound interest:

One dollar at compound interest, at twenty-four per cent., for one hundred years, would produce a sum equal to our national debt. Interest eats night and day, and the more it eats the hungrier it grows. The farmer in debt, lying awake at night, can, if he listens, hear it gnaw. If he owes nothing, he can hear his corn grow. Get out of debt as soon as possible. You have supported idle avarice and lazy economy long enough.

Compounding can apply to areas beyond finance — personal development, health, learning, relationships, and more. For each area, a small input can lead to large output, and the results build upon themselves.

Nonlinear Language Learning

When we learn a new language, it's always a good idea to start by learning the 100 or so most used words.

In all known languages, a small percentage of words make up the majority of usage. This is known as Zipf's law, after George Kingsley Zipf, who first identified the phenomenon. The most used word in a language may make up as much as 7% of all words used, while the second-most-used word is used half as much, and so on. As few as 135 words can together form half of a language (as used by native speakers).

Why Zipf's law holds true is unknown, although the concept is logical. Many languages include a large number of specialist terms that are rarely needed (including legal or anatomy terms). A small change in the frequency ranking of a word means a huge change in its usefulness.

Understanding Zipf's law is a central component of accelerated language learning. Each new word we learn from the most common 100 words will have a huge impact on our ability to communicate. As we learn less-common words, diminishing returns set in. If each word in a language were listed in order of frequency of usage, the further we moved down the list, the less useful a word would be.

Power Laws in Business, Explained by Peter Thiel

Peter Thiel, the founder of PayPal (as well as an early investor in Facebook and Palantir), considers power laws to be a crucial concept for all businesspeople to understand. In his fantastic book, *Zero to One*, Thiel writes:

Indeed, the single most powerful pattern I have noticed is that successful people find value in unexpected places, and they do this by thinking about business from first principles instead of formulas.

And:

In 1906, economist Vilfredo Pareto discovered what became the “Pareto Principle,” or the 80-20 rule, when he noticed that 20% of the people owned 80% of the land in Italy—a phenomenon that he found just as natural as the fact that 20% of the peapods in his garden produced 80% of the peas. This extraordinarily stark pattern, when a small few radically outstrip all rivals, surrounds us everywhere in the natural and social world. The most destructive earthquakes are many times more powerful than all smaller earthquakes combined. The biggest cities dwarf all mere towns put together. And monopoly businesses capture more value than millions of undifferentiated competitors. Whatever Einstein did or didn’t say, the power law—so named because exponential equations describe severely unequal distributions—is the law of the universe. It defines our surroundings so completely that we usually don’t even see it.

... [I]n venture capital, where investors try to profit from exponential growth in early-stage companies, a few companies attain exponentially greater value than all others. ... [W]e don’t live in a normal world; we live under a power law.

... The biggest secret in venture capital is that the best investment in a successful fund equals or outperforms the entire rest of the fund combined.

This implies two very strange rules for VCs. First, only invest in companies that have the potential to return the value of the entire fund. ... This leads to rule number two: because rule number one is so restrictive, there can’t be any other rules.

...[L]ife is not a portfolio: not for a startup founder, and not for any individual. An entrepreneur cannot “diversify” herself; you cannot run dozens of companies at the same time and then hope that one of them works out well. Less obvious but just as important, an individual cannot diversify his own life by keeping dozens of equally possible careers in ready reserve.

Thiel teaches a class called Startup at Stanford, where he hammers home the value of understanding power laws. In his class, he imparts copious wisdom. From Blake Masters’ notes on Class 7:

Consider a prototypical successful venture fund. A number of investments go to zero over a period of time. Those tend to happen earlier rather than later. The investments that succeed do so on some sort of exponential curve. Sum it over the life of a portfolio and you get a J curve. Early investments fail. You have to pay management fees. But then the exponential growth takes place, at least in theory. Since you start out underwater, the big question is when you make it above the water line. A lot of funds never get there.

To answer that big question you have to ask another: what does the distribution of returns in [a] venture fund look like? The naïve response is just to rank companies from best to worst according to their return in multiple of dollars invested. People tend to group investments into three buckets. The bad companies go to zero. The mediocre ones do maybe 1x, so you don’t lose much or gain much. And then the great companies do maybe 3-10x.

But that model misses the key insight that actual returns are incredibly skewed. The more a VC understands this skew pattern, the better the VC. Bad VCs tend to think the dashed line is flat, i.e. that all companies are created equal, and some just fail, spin wheels, or grow. In reality you get a power law distribution.

Thiel explains how investors can apply the mental model of power laws (more from Masters’ notes on Class 7):

... Given a big power law distribution, you want to be fairly concentrated. ... There just aren’t that many businesses that you can have the requisite high degree of conviction

about. A better model is to invest in maybe 7 or 8 promising companies from which you think you can get a 10x return. ...

Despite being rooted in middle school math, exponential thinking is hard. We live in a world where we normally don't experience anything exponentially. Our general life experience is pretty linear. We vastly underestimate exponential things.

He also cautions against over-relying on power laws as a strategy (an assertion that should be kept in mind for all mental models). From Masters' notes:

One shouldn't be mechanical about this heuristic, or treat it as some immutable investment strategy. But it actually checks out pretty well, so at the very least it compels you to think about power law distribution.

Understanding exponents and power law distributions isn't just about understanding VC. There are important personal applications too. Many things, such as key life decisions or starting businesses, also result in similar distributions.

Thiel then explains why founders should focus on one key revenue stream, rather than trying to build multiple equal ones:

Even within an individual business, there is probably a sort of power law as to what's going to drive it. It's troubling if a startup insists that it's going to make money in many different ways. The power law distribution on revenues says that one source of revenue will dominate everything else.

For example, if you're an entrepreneur who opens a coffee shop, you'll have a lot of ways you can make money. You can sell coffee, cakes, paintings, merchandise, and more. But each of those things will not contribute to your success in an equal way. While there is value in the discovery process, once you've found the variable that matters most, you should place more time on that one and less on the others. The importance of finding this variable cannot be overstated.

He also acknowledges that power laws are one of the great secrets of investing success. From Masters' notes on Class 11:

On one level, the anti-competition, power law, and distribution secrets are all secrets about nature. But they're also secrets hidden by people. That is crucial to remember. Suppose you're doing an experiment in a lab. You're trying to figure out a natural secret. But every night another person comes into the lab and messes with your results. You won't understand what's going on if you confine your thinking to the nature side of things. It's not enough to find an interesting experiment and try to do it. You have to understand the human piece too.

... We know that, per the power law secret, companies are not evenly distributed. The distribution tends to be bimodal; there are some great ones, and then there are a lot of ones that don't really work at all. But understanding this isn't enough. There is a big difference between understanding the power law secret in theory and being able to apply it in practice.

The key to all mental models is knowing the facts and being able to use the concept. As George Box said, "all models are false but some are useful." Once we grasp the basics, the best next step is to start figuring out how to apply it.

The metaphor of an unseen person sabotaging laboratory results is an excellent metaphor for how cognitive biases and shortcuts cloud our judgment.

Natural Power Laws

Anyone who has kept a lot of pets will have noticed the link between an animal's size and its lifespan. Small animals, like mice and hamsters, tend to live for a year or two. Larger ones, like dogs and cats, can live to 10-20 years, or even older in rare cases. Scaling up, even more, some whales can live for 200 years. This comes down to power laws.

Biologists have found clear links between an animal's size and its metabolism. Kleiber's law (identified by Max Kleiber) states that an animal's metabolic rate increases at three-fourths of the power of the animal's weight (mass). If an average rabbit (2 kg) weighs one

hundred times as much as an average mouse (20g), the rabbit's metabolic rate will be 32 times the mouse's. In other words, the rabbit's structure is more efficient. It all comes down to the geometry behind their mass.

This leads us to another biological power law: Smaller animals require more energy per gram of body weight, meaning that mice eat around half their body weight in dense foods each day. The reason is that, in terms of the percentage of mass, larger animals have more structure (bones, etc.) and fewer reserves (fat stores).

Research has illustrated how power laws apply to blood circulation in animals. The end units through which oxygen, water, and nutrients enter cells from the bloodstream are the same size in all animals. Only the number per animal varies. The relationship between the total area of these units and the size of the animal is a third-order power law. The distance blood travels to enter cells, and the actual volume of blood is also subject to power laws.

The Law of Diminishing Returns

As we have seen, a small change in one area can lead to a huge change in another. However, past a certain point, diminishing returns set in and more is worse. Working an hour extra per day might mean more gets done, whereas working three extra hours is likely to lead to less getting done due to exhaustion. Going from a sedentary lifestyle to running two days a week may result in greatly improved health, but stepping up to seven days a week will cause injuries. Overzealousness can turn a positive exponent into a negative exponent. For a busy restaurant, hiring an extra chef will mean that more people can be served, but hiring two new chefs might spoil the proverbial broth.

Perhaps the most underappreciated diminishing return, the one we never want to end up on the wrong side of, is the one between money and happiness.

In *David and Goliath*, Malcolm Gladwell discusses how diminishing returns relate to family incomes. Most people assume that the more money they make, the happier they and their families will be. This is true — up to a point. An income that's too low to meet basic needs makes people miserable, leading to far more physical and mental health problems. A person who goes from earning \$30,000 a year to earning \$40,000 is likely to experience a dramatic boost in happiness. However, going from \$100,000 to \$110,000 leads to a negligible change in well-being.

Gladwell writes:

The scholars who research happiness suggest that more money stops making people happier at a family income of around seventy-five thousand dollars a year. After that, what economists call "diminishing marginal returns" sets in. If your family makes seventy-five thousand and your neighbor makes a hundred thousand, that extra twenty-five thousand a year means that your neighbor can drive a nicer car and go out to eat slightly more often. But it doesn't make your neighbor happier than you, or better equipped to do the thousands of small and large things that make for being a good parent.

46. Intelligent Preparation: The World Is Multidisciplinary

We live in a society that demands specialization. Being the best means being an expert in something. Letters after your name and decades in the trenches of experience are required before you can claim to know anything. In one sense there is nothing wrong with this — specialized knowledge is required to solve problems and advance our global potential. But a byproduct of this niche focus is that it narrows the ways we think we can apply our knowledge without being called a fraud.

So we think physicists can't teach us about love; mathematicians can't instruct us on how to run a business; poets don't know squat about "my life." And bloggers can't contribute to philosophy.

I don't believe this is true.

Knowledge is hard to come by.

It takes work and commitment, and I think we owe it to ourselves to take it out of the box it comes in and experiment with it. We should blow past conformity and apply all the knowledge at our disposal to the problems and challenges we face every day.

Think about it. Over time you've picked up a lot of fundamentals about how the world works. You may have read a book about the Manhattan Project and the building of the nuclear bomb that was launched at Hiroshima. This story conveys the awesome power of self-sustaining nuclear reactions. Have you ever thought about applying those ideas to your life? You should.

47. Multiplicative Systems: Understanding The Power of Multiplying by Zero

We all learned in math class that anything times zero is zero. But if you stop XF about the idea here, you don't see all the practical applications that understanding multiplicative systems can give you in life.

Let's run through a little elementary algebra. Try to do it in your head: What's $1,506,789 \times 9,809 \times 5.56 \times 0$?

Hopefully, you didn't have to whip out the old TI-84 to solve that one. It's a zero.

This leads us to a mental model called Multiplicative Systems and understanding it can get to the heart of a lot of issues.

The Weakest Link in the Chain

Suppose you were trying to become the best basketball player in the world. You've got the following things going for you:

1. God-given talent. You're 6'9", quick, skillful, can leap out of the building, and have been the best player in a competitive city since you can remember.
2. Support. You live in a city that reveres basketball and you're raised by parents who care about your goals.
3. A proven track record. You were the player of the year in a very competitive Division 1 college conference.
4. A clear path forward. You're selected as the second overall pick in the NBA Draft by the Boston Celtics.

Sounds like you have a shot, right? As good as anyone could have, right? What would you put the odds at of this person becoming one of the better players in the world? Pretty high?

Let's add one more piece of information:

5. You've developed a cocaine habit.

What are your odds now?

This little exercise isn't an academic one, it's the sad case of Leonard "Len" Bias, a young basketball prodigy who died of a cocaine overdose after being selected to play in the NBA for the Boston Celtics in 1986. Many call Bias the best basketball player who never played professionally.

What the story of Len Bias illustrates so well is the truth that anything times zero must still be zero, no matter how large the string of numbers preceding it. In some facets of life, all of your hard work, dedication to improvement, and good fortune may still be worth nothing if there is a weak link in the chain.

Something all engineers learn very early on is that a system is no stronger than its weakest component. Take, for example, the case of a nuclear power plant. We have a very good understanding of how to make the nuclear power plant quite safe, nearly indestructible, which it must be considering the magnitude of a failure.

But in reality, what is the weakest link in the chain for most nuclear power plants? *The human beings running them.* We're part of the system! And since we've yet to perfect the human being, we have yet to perfect the nuclear power plant. How could it be otherwise?

An additive system does not work this way. In an additive system, each component adds on to one another to create the final outcome. Going back to algebra, let's say our equation was additive rather than

multiplicative: $1,506,789 \text{ plus } 9,809 \text{ plus } 5.56 \text{ plus } 0$. The answer is 1,516,603.56 — still a pretty big number!

Think of an additive system as something like a great Thanksgiving dinner. You've got a great turkey, some whipped potatoes, a mass of stuffing, and a lump of homemade cranberry sauce, and you're hanging with your family. Awesome!

Let's say the potatoes get burnt in the oven, and they're inedible. Problem? Sure, but dinner still works out just fine. Someone shows up with a pie for dessert? Great! But it won't change the dinner all that much.

The interaction of the parts makes the dinner range from good to great. Take some parts away or add new ones in, and you get a different outcome, but not a *binary*, win/lose one. The meal still happens. Additive systems and multiplicative systems react differently when components are added or taken away.

Most businesses, for example, operate in a multiplicative system. But they too often *think* they're operating in additive ones: Ever notice how some businesses will add one feature on top of another to their products but fail at basic customer service, so you leave, never to return? That's a business that thinks it's in an additive system when they really need to be resolving the big fat *zero* in the middle of the equation instead of adding more stuff.

Financial systems are, of course, multiplicative. General Motors, founded in 1908 by William Durant and C.S. Mott, came to dominate the American car market to the tune of 50% market share through a series of brilliant innovations and management practices and was for many years the dominant and most admirable corporation in America. Even today, after more than a century of competition, no American carmaker produces more automobiles than General Motors.

And yet, the original shareholders of GM ended up with a *zero* in 2008 as the company went into bankruptcy due to years of financial mismanagement. It didn't matter that they had several generations of leadership: All of that becomes naught in a multiplicative system.

On a smaller scale, take the case of a young corporate climber who feels they just can't get ahead. They seem to have all their ducks in a row: great resume, great background, great experience...the problem is that they suck at dealing with other people and treat others like stepping stones. That's a *zero* that can negate *all* of the big numbers preceding it. The rest doesn't matter.

And so we arrive at the "must be true" conclusion that understanding when you're in an additive system versus a multiplicative system, and which components need absolute reliability for the system to work, is a critical model to have in your head. Multiplicative thinking is a model related to the greater idea of systems thinking, another mental model well worth acquiring.

48. The Skill You've Never Been Taught: How to Think Better

No skill is more valuable or harder to come by than the ability to critically think through problems.

Thinking better than others means you'll have more free time and fewer problems. If you can't think well, you'll spend a lot of time fixing avoidable mistakes.

If you stop thinking when most people stop thinking, you'll come to the same conclusions most people come to. Thinking is hard, so it's natural that most people stop as soon as possible. We get the gist of something and move on to the next problem.

Where do the ideas come from? Mine come from sitting and thinking.

Ed Thorp

How can we learn to think better?

One answer comes from the lecture Solitude and Leadership by William Deresiewicz, author of the *New York Times* bestseller *Excellent Sheep: The Miseducation of the American Elite and the Way to a Meaningful Life*. The entire speech, which was delivered at Westpoint, is worth reading, but here is the essential takeaway.

Learning How To Think

Let's start with how you don't learn to think. A study by a team of researchers at Stanford came out a couple of months ago. The investigators wanted to figure out how today's college students were able to multitask so much more effectively than adults. How do they manage to do it, the researchers asked? The answer, they discovered—and this is by no means what they expected—is that they don't. The enhanced cognitive abilities the investigators expected to find, the mental faculties that enable people to multitask effectively, were simply not there. In other words, people do not multitask effectively. And here's the really surprising finding: the more people multitask, the worse they are, not just at other mental abilities, but at multitasking itself.

One thing that made the study different from others is that the researchers didn't test people's cognitive functions while they were multitasking. They separated the subject group into high multitaskers and low multitaskers and used a different set of tests to measure the kinds of cognitive abilities involved in multitasking. They found that in every case the high multitaskers scored worse. They were worse at distinguishing between relevant and irrelevant information and ignoring the latter. In other words, they were more distractible. They were worse at what you might call "mental filing": keeping information in the right conceptual boxes and being able to retrieve it quickly. In other words, their minds were more disorganized. And they were even worse at the very thing that defines multitasking itself: switching between tasks.

Multitasking, in short, is not only not thinking, it impairs your ability to think. Thinking means concentrating on one thing long enough to develop an idea about it. Not learning other people's ideas, or memorizing a body of information, however much those may sometimes be useful. Developing your own ideas. In short, thinking for yourself. You simply cannot do that in bursts of 20 seconds at a time, constantly interrupted by Facebook messages or Twitter tweets, or fiddling with your iPod, or watching something on YouTube.

I find for myself that my first thought is never my best thought. My first thought is always someone else's; it's always what I've already heard about the subject, always the conventional wisdom. It's only by concentrating, sticking to the question, being patient, letting all the parts of my mind come into play, that I arrive at an original idea. By giving my brain a chance to make associations, draw connections, take me by surprise. And often even that idea doesn't turn out to be very good. I need time to think about it, too, to make mistakes and recognize them, to make false starts and correct them, to outlast my impulses, to defeat my desire to declare the job done and move on to the next thing.

I used to have students who bragged to me about how fast they wrote their papers. I would tell them that the great German novelist Thomas Mann said that a writer is someone for whom writing is more difficult than it is for other people. The best writers write much more slowly than everyone else, and the better they are, the slower they write. James Joyce wrote Ulysses, the greatest novel of the 20th century, at the rate of about a hundred words a day—half the length of the selection I read you earlier from Heart of Darkness—for seven years. T. S. Eliot, one of the greatest poets our country has ever produced, wrote about 150 pages of poetry over the course of his entire 25-year career. That's half a page a month. So it is with any other form of thought. You do your best thinking by slowing down and concentrating.

Improving Thinking

The best way to improve your thinking ability is to spend time thinking.

Immersing ourselves in a subject and giving it our full attention offers insights that can't be gained simply by skimming on the surface.

How can we force ourselves to spend more time thinking?

One way to engage with an idea is to write about it.

If you're thinking without writing, you only think you're thinking.

Leslie Lamport

While we naturally understand that writing is a good way to share ideas with others, we under-appreciate just how much good writing helps us think about an idea ourselves.

Writing is not only a means of communication, it enables us to practice reasoning.

Writing forces you to slow down, focus, and think deeply. In a world where attention is fragmented into seconds, thinking becomes more reactive than reasoned. Only when take time to play with our ideas can we hope to think about them substantially. Writing requires sticking with something a little longer and developing a deeper understanding.

Writing is the process by which we realize we do not understand and the process by which we come to understand.

Writing requires the compression of an idea. When done poorly, compression removes crucial information. When done well, compression keeps the essential and removes the rest. Compression requires both thinking and clarity, which is one reason writing is an important aid to thinking.

It's only by concentrating, sticking to the question, being patient, letting all the parts of my mind come into play, that I arrive at an original idea. By giving my brain a chance to make associations, draw connections, take me by surprise.

— William Deresiewicz

Good writing gives poor thinking nowhere to hide. It's easy to read and flows. Poor writing is a drag as your mind is forced to sift through the obfuscation to try and pull out the right information. Poor writing is a strong indication of poor thinking.

Good writing requires thinking. Thinking takes time. Good thinking is expensive, but bad thinking costs a fortune.

The Bottom Line

The process of writing helps you think through an idea.

Writing forces you to test your thinking. Strangers can't know your thoughts, unless you put them into words. So one way to test your ideas is to let other people read them.

Take the time to write down your thoughts.

49. Mental Model: Bias from Insensitivity to Sample Size

The widespread misunderstanding of randomness causes a lot of problems.

Today we're going to explore a concept that causes a lot of human misjudgment. It's called the bias from insensitivity to sample size, or, if you prefer, the law of small numbers.

Insensitivity to small sample sizes causes a lot of problems.

* * *

If I measured one person, who happened to measure 6 feet, and then told you that everyone in the whole world was 6 feet, you'd intuitively realize this is a mistake. You'd say, you can't measure only one person and then draw such a conclusion. To do that you'd need a much larger sample.

And, of course, you'd be right.

While simple, this example is a key building block to our understanding of how insensitivity to sample size can lead us astray.

As Stuard Suterhland writes in Irrationality:

Before drawing conclusions from information about a limited number of events (a sample) selected from a much larger number of events (the population) it is important to understand something about the statistics of samples.

In Thinking, Fast and Slow, Daniel Kahneman writes "A random event, by definition, does not lend itself to explanation, but collections of random events do behave in a highly regular fashion." Kahneman continues, "extreme outcomes (both high and low) are more likely to be found in small than in large samples. This explanation is not causal."

We all intuitively know that "the results of larger samples deserve more trust than smaller samples, and even people who are innocent of statistical knowledge have heard about this law of large numbers."

The principle of regression to the mean says that as the sample size grows larger results should converge to a stable frequency. So, if we're flipping coins, and measuring the proportion of times that we get heads, we'd expect it to approach 50% after some large sample size of, say, 100 but not necessarily 2 or 4.

In our minds, we often fail to account for the accuracy and uncertainty with a given sample size.

While we all understand it intuitively, it's hard for us to realize in the moment of processing and decision making that larger samples are better representations than smaller samples. We understand the difference between a sample size of 6 and 6,000,000 fairly well but we don't, intuitively, understand the difference between 200 and 3,000.

* * *

This bias comes in many forms.

In a telephone poll of 300 seniors, 60% support the president.

If you had to summarize the message of this sentence in exactly three words, what would they be? Almost certainly you would choose "elderly support president." These words provide the gist of the story. The omitted details of the poll, that it was done on the phone with a sample of 300, are of no interest in themselves; they provide background information that attracts little attention." Of course, if the sample was extreme, say 6 people, you'd question it. Unless you're fully mathematically equipped, however, you'll intuitively judge the sample size and you may not react differently to a sample of, say, 150 and 3000. That, in a nutshell, is exactly the meaning of the statement that "people are not adequately sensitive to sample size."

Part of the problem is that we focus on the story over reliability, or, robustness, of the results.

System one thinking, that is our intuition, is "not prone to doubt. It suppresses ambiguity and spontaneously constructs stories that are as coherent as possible. Unless the

message is immediately negated, the associations that it evokes will spread as if the message were true.”

Considering sample size, unless it's extreme, is not a part of our intuition.

Kahneman writes:

The exaggerated faith in small samples is only one example of a more general illusion – we pay more attention to the content of messages than to information about their reliability, and as a result end up with a view of the world around us that is simpler and more coherent than the data justify. Jumping to conclusions is a safer sport in the world of our imagination than it is in reality.

* * *

In engineering, for example, we can encounter this in the evaluation of precedent.

Steven Vick, writing in Degrees of Belief: Subjective Probability and Engineering Judgment, writes:

If something has worked before, the presumption is that it will work again without fail. That is, the probability of future success conditional on past success is taken as 1.0.

Accordingly, a structure that has survived an earthquake would be assumed capable of surviving with the same magnitude and distance, with the underlying presumption being that the operative causal factors must be the same. But the seismic ground motions are quite variable in their frequency content, attenuation characteristics, and many other factors, so that a precedent for a single earthquake represents a very small sample size.

Bayesian thinking tells us that a single success, absent of other information, raises the likelihood of survival in the future.

In a way this is related to robustness. The more you've had to handle and you still survive the more robust you are.

Let's look at some other examples.

* * *

Hospital

Daniel Kahneman and Amos Tversky demonstrated our insensitivity to sample size with the following question:

A certain town is served by two hospitals. In the larger hospital about 45 babies are born each day, and in the smaller hospital about 15 babies are born each day. As you know, about 50% of all babies are boys. However, the exact percentage varies from day to day. Sometimes it may be higher than 50%, sometimes lower. For a period of 1 year, each hospital recorded the days on which more than 60% of the babies born were boys. Which hospital do you think recorded more such days?

1. The larger hospital
2. The smaller hospital
3. About the same (that is, within 5% of each other)

Most people incorrectly choose 3. The correct answer is, however, 2.

In Judgment in Managerial Decision Making, Max Bazerman explains:

Most individuals choose 3, expecting the two hospitals to record a similar number of days on which 60 percent or more of the babies born are boys. People seem to have some basic idea of how unusual it is to have 60 percent of a random event occurring in a specific direction. However, statistics tells us that we are much more likely to observe 60 percent of male babies in a smaller sample than in a larger sample.” This effect is easy to understand. Think about which is more likely: getting more than 60 percent heads in three flips of coin or getting more than 60 percent heads in 3,000 flips.

* * *

Another interesting example comes from Poker.

Over short periods of time luck is more important than skill. The more luck contributes to the outcome, the larger the sample you'll need to distinguish between someone's skill and pure chance.

David Einhorn explains.

People ask me "Is poker luck?" and "Is investing luck?"

The answer is, not at all. But sample sizes matter. On any given day a good investor or a good poker player can lose money. Any stock investment can turn out to be a loser no matter how large the edge appears. Same for a poker hand. One poker tournament isn't very different from a coin-flipping contest and neither is six months of investment results. On that basis luck plays a role. But over time – over thousands of hands against a variety of players and over hundreds of investments in a variety of market environments – skill wins out.

As the number of hands played increases, skill plays a larger and larger role and luck plays less of a role.

* * *

But this goes way beyond hospitals and poker. Baseball is another good example. Over a long season, odds are the best teams will rise to the top. In the short term, anything can happen. If you look at the standing 10 games into the season, odds are they will not be representative of where things will land after the full 162 game season. In the short term, luck plays too much of a role.

In Moneyball, Michael Lewis writes "In a five-game series, the worst team in baseball will beat the best about 15% of the time."

* * *

If you promote people or work with colleagues you'll also want to keep this bias in mind. If you assume that performance at work is some combination of skill and luck you can easily see that sample size is relevant to the reliability of performance.

That performance sampling works like anything else, the bigger the sample size the bigger the reduction in uncertainty and the more likely you are to make good decisions.

This has been studied by one of my favorite thinkers, James March. He calls it the false record effect.

He writes:

False Record Effect. A group of managers of identical (moderate) ability will show considerable variation in their performance records in the short run. Some will be found at one end of the distribution and will be viewed as outstanding; others will be at the other end and will be viewed as ineffective. The longer a manager stays in a job, the less the probable difference between the observed record of performance and actual ability. Time on the job increased the expected sample of observations, reduced expected sampling error, and thus reduced the change that the manager (or moderate ability) will either be promoted or exit.

Hero Effect. Within a group of managers of varying abilities, the faster the rate of promotion, the less likely it is to be justified. Performance records are produced by a combination of underlying ability and sampling variation. Managers who have good records are more likely to have high ability than managers who have poor records, but the reliability of the differentiation is small when records are short.

(I realize promotions are a lot more complicated than I'm letting on. Some jobs, for example, are more difficult than others. It gets messy quickly and that's part of the problem. Often when things get messy we turn off our brains and concoct the simplest explanation we can. Simple but wrong. I'm only pointing out that sample size is one input into the decision. I'm by no means advocating an "experience is best" approach, as that comes with a host of other problems.)

* * *

This bias is also used against you in advertising.

The next time you see a commercial that says “4 out of 5 Doctors recommend” These results are meaningless without knowing the sample size. Odds are pretty good that the sample size is 5.

* * *

Large sample sizes are not a panacea. Things change. Systems evolve and faith in those results can be unfounded as well.

The key, at all times, is to think.

This bias leads to a whole slew of things, such as:

- under-estimating risk
- over-estimating risk
- undue confidence in trends/patterns
- undue confidence in the lack of side-effects/problems

The Bias from insensitivity to sample size is part of the Farnam Street latticework of mental models.

50. Daniel Dennett: How to Make Mistakes

In *Intuition Pumps And Other Tools for Thinking*, Daniel Dennett, one of the world's leading philosophers offers a trove of mind-stretching thought experiments, which he calls "imagination-extendors and focus-holders" (intuition pumps). They allow us to "think reliably and even gracefully about really hard questions."

The first intuition pump is on mistakes.

More specifically, how to make mistakes and the keys to good mistakes.

History Rhymes

The history of philosophy is in large measure the history of very smart people making very tempting mistakes, and if you don't know the history, you are doomed to making the same darn mistakes all over again.

Learning

Mistakes are not just opportunities for learning; they are, in an important sense, the only opportunity for learning or making something truly new. Before there can be learning, there must be learners. There are only two non-miraculous ways for learners to come into existence: they must either evolve or be designed and built by learners that evolved. Biological evolution proceeds by a grand, inexorable process of trial and error — and without the errors the trials wouldn't accomplish anything.

Evolution is the Enabling Process of Knowledge

Evolution is one of the central themes of this book, as all my books, for the simple reason that it is the central, enabling process not only of life but also of knowledge and learning and understanding. If you attempt to make sense of the world of ideas and meanings, free will and morality, art and science and even philosophy itself without a sound and quite detailed knowledge of evolution, you have one hand tied behind your back. ... For evolution, which knows nothing, the steps into novelty are blindly taken by mutations, which are random copying "errors" in DNA.

The Key to Good Mistakes

The chief trick to making good mistakes is not to hide them — especially not from yourself. Instead of turning away in denial when you make a mistake, you should become a connoisseur of your own mistakes, turning them over in your mind as if they were works of art, which in a way they are. The fundamental reaction to any mistake ought to be this: "Well, I won't do that again!" Natural selection doesn't actually think the thought; it just wipes out the goofers before they can reproduce; natural selection won't do that again, at least not as often. Animals that can learn—learn not to make that noise, touch that wire, eat that food—have something with a similar selective force in their brains. (B. F. Skinner and the behaviorists understood the need for this and called it "reinforcement" learning; that response is not reinforced and suffers "extinction.") We human beings carry matters to a much more swift and efficient level. We can actually think the thought, reflecting on what we have just done: "Well, I won't do that again!" And when we reflect, we confront directly the problem that must be solved by any mistake-maker: what, exactly, is that? What was it about what I just did that got me into all this trouble? The trick is to take advantage of the particular details of the mess you've made, so that your next attempt will be informed by it and not just another blind stab in the dark.

We have all heard the forlorn refrain "Well, it seemed like a good idea at the time!" This phrase has come to stand for the rueful reflection of an idiot, a sign of stupidity, but in fact we should appreciate it as a pillar of wisdom. Any being, any agent, who can truly say, "Well, it seemed like a good idea at the time!" is standing on the threshold of brilliance. We human beings pride ourselves on our intelligence, and one of its hall marks is that we can remember our previous thinking, and reflect on it—on how it seemed, on why it was tempting in the first place, and then about what went wrong.

[...]

So when you make a mistake, you should learn to take a deep breath, grit your teeth, and then examine your own recollections of the mistake as ruthlessly and as dispassionately as you can manage. It's not easy. The natural human reaction to making a mistake is embarrassment and anger (we are never angrier than when we are angry at ourselves), and you have to work hard to overcome these emotional reactions. Try to acquire the weird practice of savoring your mistakes, delighting in uncovering the strange quirks that led you astray. Then, once you have sucked out all the goodness to be gained from having made them, you can cheerfully set them behind you, and go on to the next big opportunity. But that is not enough: you should actively seek out opportunities to make grand mistakes, just so you can then recover from them.

Natural Selection

Every organism on the earth dies sooner or later after one complicated life story or another. How on earth could natural selection see through the fog of all these details in order to figure out what positive factors to “reward” with offspring and what negative factors to “punish” with childless death? Can it really be that some of our ancestors’ siblings died childless because their eyelids were the wrong shape? If not, how could the process of natural selection explain why our eyelids came to have the excellent shapes they have? Part of the answer is familiar: following the old adage: “If it ain’t broke, don’t fix it,” leave almost all of your old, conservative design solutions in place and take your risks with a safety net in place. Natural selection automatically conserves whatever has worked up to now, and fearlessly explores innovations large and small; the large ones almost always lead immediately to death. A terrible waste, but nobody’s counting. Our eyelids were mostly designed by natural selection long before there were human beings or even primates or even mammals.

Card Tricks

Here is a technique that card magicians—at least the best of them—exploit with amazing results. (I don’t expect to incur the wrath of the magicians for revealing this trick to you, since this is not a particular trick but a deep general principle.) A good card magician knows many tricks depend on luck—they don’t always work, or even often work. There are some effects—they can hardly be called tricks—that might work only once in a thousand times! Here is what you do: You start by telling the audience you are going to perform a trick, and without telling them what trick you are doing, you go for the one-in-a-thousand effect. It almost never works, of course, so you glide seamlessly into a second try, for an effect that works about one time in a hundred, perhaps. When it too fails (as it almost always will) you slide into effect #3, which only works about one time in ten, so you’d better be ready with effect #4 which works half the time (let’s say), and if all else fails (and by this time, usually one of the earlier safety nets will have kept you out of this worst case), you have a failsafe effect, which won’t impress the crowd very much but at least it’s a surefire trick. In the course of a whole performance, you will be very unlucky indeed if you always have to rely on your final safety net, and whenever you achieve one of the higher-flying effects, the audience will be stupefied. “Impossible! How on earth could you have known that was my card?” Aha! You didn’t know, but you had a cute way of taking a hopeful stab in the dark that paid off. By hiding the “error” cases from view, you create a “miracle”.

Evolution Works The Same Way

Evolution works the same way: all the dumb mistakes tend to be invisible, so all we see is a stupendous string of triumphs. For instance, the vast majority — way over 90 percent — of all the creatures that have ever lived died childless, but not a single one of your ancestors suffered that fate. Talk about a line of charmed lives!

One big difference between the discipline of science and the discipline of stage magic is that while magicians conceal their false starts from the audience as best they can, in science you make your mistakes in public. You show them off so that everybody can learn from them. ... It is not so much that our brains are bigger or more powerful, or even that

we have the knack of reflecting on our own past errors, but that we share the benefits that our individual brains have won by their individual histories of trial and error.

I am amazed at how many really smart people don't understand that you can make big mistakes in public and emerge none the worse for it.

We all know people, perhaps ourselves included, who will go to great lengths to avoid admitting they were wrong. But Dennett argues:

Actually, people love it when somebody admits to making a mistake. All kinds of people love pointing out mistakes. Generous-spirited people appreciate your giving them the opportunity to help, and acknowledging it when they succeed in helping you; mean-spirited people enjoy showing you up. Let them! Either way we all win.

Of course, in general, people do not enjoy correcting the stupid mistakes of others. You have to have something worth correcting, something original to be right or wrong about ...

51. The Laws of Simplicity

“Simplicity is about subtracting the obvious,
and adding the meaningful.”

John Maeda is a graphic designer and computer scientist. His book, The Laws of Simplicity, proposes ten laws for simplifying complex systems in business and life. Think of it as simplicity 101.

Simplicity = Sanity

Technology has made our lives more full, yet at the same time we've become uncomfortably "full."

Ten Laws

1 REDUCE The simplest way to achieve simplicity is through thoughtful reduction.

2 ORGANIZE Organization makes a system of many appear fewer.

3 TIME Savings in time feel like simplicity.

4 LEARN Knowledge makes everything simpler.

5 DIFFERENCES Simplicity and complexity need each other.

6 CONTEXT What lies in the periphery of simplicity is definitely not peripheral.

7 EMOTION More emotions are better than less.

8 TRUST In simplicity we trust.

9 FAILURE Some things can never be made simple.

10 THE ONE Simplicity is about subtracting the obvious, and adding the meaningful.

Three Keys

In addition to the ten Laws, Maeda offers three Keys to achieving simplicity in the technology domain.

1 AWAY More appears like less by simply moving it far, far away.

2 OPEN Openness simplifies complexity.

3 POWER Use less, gain more.

Let's take a look at a few of these.

The simplest way to achieve simplicity.

The simplest way to achieve simplicity is through thoughtful reduction. When in doubt, just remove. But be careful of what you remove. ... When it is possible to reduce a system's functionality without significant penalty, true simplification is realized.

What is simplicity about?

Simplicity is about the unexpected pleasure derived from what is likely to be insignificant and would otherwise go unnoticed.

The relationship between space and clutter

At first, a larger home lowers the clutter to space ratio. But ultimately, the greater space enables more clutter.

Small changes in organization create big differences in a design.

Squint at the world.

The best designers in the world all squint when they look at something. They squint to see the forest from the trees-to find the right balance. Squint at the world. You will see more, by seeing less.

Time Savings

When forced to wait, life seems unnecessarily complex. Savings in time feel like simplicity. ... A shot from the doctor hurts less when it happens quickly, and even less when we know that the shot will save our lives.

Knowledge makes everything simpler.

This is true for any object, no matter how difficult. The problem with taking time to learn a task is that you often feel you are wasting time, a violation of the third Law. We are well aware of the dive-in-head-first approach-"I don't need the instructions, let me just do it." But in fact this method often takes longer than following the directions in the manual.

Good Design

The best designers marry function with form to create intuitive experiences that we understand immediately-no lessons (or cursing) needed. Good design relies to some extent on the ability to instill a sense of instant familiarity.

Need to Know vs. Nice to Know

Difficult tasks seem easier when they are “need to know” rather than “nice to know.” A course in history, mathematics, or chemistry is nice to know for a teenager, but completing driver’s education satisfies a fundamental need for autonomy.

Simplicity and complexity need each other.

The more complexity there is in the market, the more that something simpler stands out.

It’s best to preserve emptiness because nothing is an important something.

The opportunity lost by increasing the amount of blank space is gained back with enhanced attention on what remains. More white space means that less information is presented. In turn, proportionately more attention shall be paid to that which is made less available. When there is less, we appreciate everything much more.

Some things can never be made simple. Complexity can be beautiful.

Concentrate on the deep beauty of a flower. Notice the many thin, delicate strands that emanate from the center and the sublime gradations of hue that occur even in the simplest white blossom. Complexity can be beautiful. At the same time, the beautiful simplicity of planting a seed and just adding water lies at even the most complex flower’s beginning.

Remember, “Technology and life only become complex if you let it be so.”

52. The Timeless Parable of Mr. Market

There is no one better to explain the concept of Mr. Market than Warren Buffett, who has used to to make billions of dollars and remain calm when all around him were losing their heads.

In the 1987 letter to Berkshire Hathaway shareholders, Buffett unfolds the concept for us. *Ben Graham, my friend and teacher, long ago described the mental attitude toward market fluctuations that I believe to be most conducive to investment success. He said that you should imagine market quotations as coming from a remarkably accommodating fellow named Mr. Market who is your partner in a private business. Without fail, Mr. Market appears daily and names a price at which he will either buy your interest or sell you his. Even though the business that the two of you own may have economic characteristics that are stable, Mr. Market's quotations will be anything but. For, sad to say, the poor fellow has incurable emotional problems. At times he feels euphoric and can see only the favorable factors affecting the business. When in that mood, he names a very high buy-sell price because he fears that you will snap up his interest and rob him of imminent gains. At other times he is depressed and can see nothing but trouble ahead for both the business and the world. On these occasions, he will name a very low price, since he is terrified that you will unload your interest on him.*

Mr. Market has another endearing characteristic: He doesn't mind being ignored. If his quotation is uninteresting to you today, he will be back with a new one tomorrow. Transactions are strictly at your option. Under these conditions, the more manic-depressive his behavior, the better for you.

But, like Cinderella at the ball, you must heed one warning or everything will turn into pumpkins and mice: Mr. Market is there to serve you, not to guide you. It is his pocketbook, not his wisdom, that you will find useful. If he shows up some day in a particularly foolish mood, you are free to either ignore him or to take advantage of him, but it will be disastrous if you fall under his influence. Indeed, if you aren't certain that you understand and can value your business far better than Mr. Market, you don't belong in the game. As they say in poker, "If you've been in the game 30 minutes and you don't know who the patsy is, you're the patsy."

Ben's Mr. Market allegory may seem out-of-date in today's investment world, in which most professionals and academicians talk of efficient markets, dynamic hedging and betas. Their interest in such matters is understandable, since techniques shrouded in mystery clearly have value to the purveyor of investment advice. After all, what witch doctor has ever achieved fame and fortune by simply advising "Take two aspirins"? The value of market esoterica to the consumer of investment advice is a different story. In my opinion, investment success will not be produced by arcane formulae, computer programs or signals flashed by the price behavior of stocks and markets. Rather an investor will succeed by coupling good business judgment with an ability to insulate his thoughts and behavior from the super-contagious emotions that swirl about the marketplace. In my own efforts to stay insulated, I have found it highly useful to keep Ben's Mr. Market concept firmly in mind.

Following Ben's teachings, Charlie and I let our marketable equities tell us by their operating results – not by their daily, or even yearly, price quotations – whether our investments are successful. The market may ignore business success for a while, but eventually will confirm it. As Ben said: "In the short run, the market is a voting machine but in the long run it is a weighing machine." The speed at which a business's success is recognized, furthermore, is not that important as long as the company's intrinsic value is increasing at a satisfactory rate. In fact, delayed recognition can be an advantage: It may give us the chance to buy more of a good thing at a bargain price.

Of course, this concept can be applied outside of stock markets as well.

“In the short run, the market is a voting machine but in the long run it is a weighing machine.”

— Ben Graham

52. Mastering Success: Navigating Within Your Circle of Competence

Understanding where you have an edge and where you don't can help you prevent problems, spot opportunities others miss, and rapidly learn.

We all have a circle of competence – an area in which we have a lot of earned knowledge. The size of that circle is not important. What is important is knowing when you are approaching the perimeter.

Within your circle of competence, you operate with an advantage. As you approach the perimeter (the limitations of your knowledge), your advantage starts to reduce. As you cross the perimeter, not only does your advantage vanish, but it transfers to other people. Suddenly, you find yourself playing in an area where others have an edge.

Just because you are good at something doesn't mean you are good at everything.

A Grandmaster in chess is at home on the chessboard, but those skills don't translate into being competent in other areas of life, such as cooking in the kitchen. In fact, it's often the case that extreme skills in one area create extreme weaknesses in others.

I want to think about things where I have an advantage over other people. I don't want to play a game where people have an advantage over me. I don't play in a game where other

people are wise and I am stupid. I look for a game where I am wise and they are stupid. And believe me it works better. God bless our stupid competitors. They make us rich.

Charlie Munger

As we cross the perimeter from what we know to what we don't, confidence does not diminish as fast as competence. The biggest risk when operating outside of your circle of competence is what you don't see.

While most people are concerned with the *size* of their circle, it's a lot more important to know when you are approaching the *perimeter*.

Circle Of Competence

I'm no genius. I'm smart in spots—but I stay around those spots.

Tom Watson Sr., Founder of IBM

Warren Buffett described circle of competence using one of his former business managers, Rose Blumkin, a Russian immigrant with poor English who built the largest furniture store in Nebraska:

I couldn't have given her \$200 million worth of Berkshire Hathaway stock when I bought the business because she doesn't understand stock. She understands cash. She understands furniture. She understands real estate. She doesn't understand stocks, so she doesn't have anything to do with them. If you deal with Mrs. B in what I would call her circle of competence... She is going to buy 5,000 end tables this afternoon (if the price is right). She is going to buy 20 different carpets in odd lots, and everything else like that [snaps fingers] because she understands carpet. She wouldn't buy 100 shares of General Motors if it was at 50 cents a share.

It did not hurt Mrs. B to have such a narrow area of competence. In fact, one could argue the opposite. Her rigid devotion to that area allowed her to focus. Only by focusing on one thing could she overcome her handicaps and achieve such extreme success.

Charlie Munger applies the concept to life in general. He sought to answer the essential question: Where should we devote our limited time to achieve the most success?

You have to figure out what your own aptitudes are. If you play games where other people have the aptitudes and you don't, you're going to lose. And that's as close to certain as any prediction that you can make. You have to figure out where you've got an edge. And you've got to play within your own circle of competence.

If you want to be the best tennis player in the world, you may start out trying and soon find out that it's hopeless—that other people blow right by you. However, if you want to become the best plumbing contractor in Bemidji, that is probably doable by two-thirds of you. It takes a will. It takes the intelligence. But after a while, you'd gradually know all about the plumbing business in Bemidji and master the art. That is an attainable objective, given enough discipline. And people who could never win a chess tournament or stand in center court in a respectable tennis tournament can rise quite high in life by slowly developing a circle of competence—which results partly from what they were born with and partly from what they slowly develop through work.

It becomes easier to stay within your circle of competence when you focus on outcome over ego.

When asked why Berkshire Hathaway hasn't invested in pharmaceuticals, Charlie Munger responded:

By and large, we haven't invested in pharmaceuticals because we've got no edge. I don't know enough about biology and medicine and chemistry to have any edge in guessing

which new pharmaceutical attempt is likely to succeed and other people who know those things, not that they have perfect knowledge, but it's way better than mine. Why in the hell would I play against other people in a game where they're much better at it than I am when I'm playing for something desperately important to me like a way of feeding my family. So of course, we didn't go near it.

I would argue that — in practical life, if you want to succeed, you got to do two things. You got to have a certain amount of confidence. And you have to know what you know and what you don't know. You have to know the edge of your competency. And if you know the edge of your competency, you're a much safer thinker and a much safer investor than you are if you don't know it.

It's better to have an IQ of 160 and think it's 150 than an IQ of 160 and think it's 200. That guy is going to kill you because he doesn't know the edge of his own competence and he thinks he knows everything.

Partly, Warren and I, we pretty much know what we know and what we don't know, what we're good at, what we're not good at. And one of the things we're not good at is guessing which new pharmaceuticals. So we don't even look at it. After all, it's a big universe out there and if we have to leave a certain kind of investment behind because we lack the capacity to deal with it as well as some other people. That's all right. We don't need an infinite number of opportunities.

To improve the odds of success in life and business, understand the perimeter of your circle of competence and operate well inside. Over time, work to expand that circle, but don't fool yourself about where the perimeter is, and never be afraid to say, "I don't know."

60. Margin of Safety: An Introduction to the Mental Model

Previously on Farnam Street, we covered the idea of Redundancy — a central concept in both the world of engineering and in practical life. Today we're going to explore a related concept: Margin of Safety.

The margin of safety is another concept rooted in engineering and quality control. Let's start there, then see where else our model might apply in practical life, and lastly, where it might have limitations.

* * *

Consider a highly-engineered jet engine part. If the part were to fail, the engine would also fail, perhaps at the worst possible moment—while in flight with passengers on board. Like most jet engine parts, let us assume the part is replaceable over time—though we don't want to replace it too often (creating prohibitively high costs), we don't expect it to last the lifetime of the engine. We design the part for 10,000 hours of average flying time.

That brings us to a central question: After how many hours of service do we replace this critical part? The easily available answer might be 9,999 hours. Why replace it any sooner than we have to? Wouldn't that be a waste of money?

The first problem is, we know nothing of the composition of the 10,000 hours any individual part has gone through. Were they 10,000 particularly tough hours, filled with turbulent skies? Was it all relatively smooth sailing? Somewhere in the middle?

Just as importantly, how confident are we that the part will really last the full 10,000 hours? What if it had a slight flaw during manufacturing? What if we made an assumption about its reliability that was not conservative enough? What if the material degraded in bad weather to a degree we didn't foresee?

The challenge is clear, and the implication obvious: we do not wait until the part has been in service for 9,999 hours. Perhaps at 7,000 hours, we seriously consider replacing the part, and we put a hard stop at 7,500 hours.

The difference between waiting until the last minute and replacing it comfortably early gives us a margin of safety. The sooner we replace the part, the more safety we have—by not pushing the boundaries, we leave ourselves a cushion. (Ever notice how your gas tank indicator goes on long before you're really on empty? It's the same idea.)

The principle is essential in bridge building. Let's say we calculate that, on an average day, a proposed bridge will be required to support 5,000 tons at any one time. Do we build the structure to withstand 5,001 tons? I'm not interested in driving on that bridge. What if we get a day with much heavier traffic than usual? What if our calculations and estimates are a little off? What if the material weakens over time at a rate faster than we imagined? To account for these, we build the bridge to support 20,000 tons. Only now do we have a margin of safety.

This fundamental engineering principle is useful in many practical areas of life, even for non-engineers. Let's look at one we all face.

* * *

Take a couple earning \$100,000 per year after taxes, or about \$8,300 per month. In designing their life, they must necessarily decide what standard of living to enjoy. (The part which can be quantified, anyway.) What sort of monthly expenses should they allow themselves to accumulate?

One all-too-familiar approach is to build in monthly expenses approaching \$8,000. A \$4,000 mortgage, \$1,000 worth of car payments, \$1,000/month for private schools...and so on. The couple rationalizes that they have "earned" the right live large.

However, what if there are some massive unexpected expenditures thrown their way? (In the way life often does.) What if one of them lost their job and their combined monthly income dropped to \$4,000?

The couple must ask themselves whether the ensuing misery is worth the lavish spending. If they kept up their \$8,000/month spending habit after a loss of income, they would have to choose between two difficult paths: Rapidly eating into their savings or considerably downsizing their life. Either is likely to cause extreme misery from the loss of long-held luxuries.

Thinking in reverse, how can we avoid the potential misery?

A common refrain is to tell the couple to make sure they've stashed away some money in case of emergency, to provide a buffer. Often there is a specific multiple of current spending we're told to have in reserve—perhaps 6-12 months. In this case, savings of \$48,000-\$96,000 should suffice.

However, is there a way we can build them a much larger margin for error?

Let's say the couple decides instead to permanently limit their monthly spending to \$4,000 by owning a smaller house, driving less expensive cars, and trusting their public schools.

What happens?

Our margin of safety now compounds. Obviously, a savings rate exceeding 50% will rapidly accumulate in their favor — \$4,300 put away by the first month, \$8,600 by the second month, and so on. The mere act of systematically underspending their income rapidly gives them a cushion without much trying. If an unexpected expenditure comes up, they'll almost certainly be ready.

The unseen benefit and the extra margin of safety in this choice comes if either spouse loses their income – either by choice (perhaps to care for a child) or by bad luck (health issues). In this case, not only has a high savings rate accumulated in their favor, but because their spending is systematically low, they can avoid tapping it altogether! Their savings simply stop growing temporarily while they live on one income. This sort of “belt and suspenders” solution is the essence of margin-of-safety thinking.

(On a side note: Let's take it even one step further. Say their former \$8,000 monthly spending rate meant they probably could not retire until age 70, given their current savings rate, investment choices, and desired lifestyle post-retirement. Reducing their needs to \$4,000 not only provides them much needed savings, quickly accelerating their retirement date, but they now need even less to retire on in the first place. Retiring at 70 can start to look like retiring at 45 in a hurry.)

* * *

Clearly, the margin of safety model is very powerful, and we're wise to use it whenever possible to avoid failure. But it has limitations.

One obvious issue, most salient in the engineering world, comes in the tradeoff with time and money. Given an unlimited runway of time and the most expensive materials known to mankind, it's likely that we could “fail-proof” many products to such a ridiculous degree as to be impractical in the modern world.

For example, it's possible to imagine Boeing designing a plane that would have a fail rate indistinguishable from zero, with parts being replaced 10% into their useful lives, built with rare but super-strong materials, etc.—so long as the world was willing to pay \$25,000 for a coach seat from Boston to Chicago. Given the impracticability of that scenario, our tradeoff has been to accept planes that are not “fail-proof,” but merely extremely unlikely to fail, to give the world safe enough air travel at an affordable cost. This tradeoff has been enormously wise and helpful to the world. Simply put, the margin-of-safety idea can be pushed into farce without careful judgment.

* * *

This brings us to another limitation of the model, which is the failure to engage in “total systems” thinking.

“The reliability that matters is not the simple reliability of one component of a system, but the final reliability of the total control system.”

— Garrett Hardin in Filters Against Folly

Let's return to the Boeing analogy. Say we did design the safest and most reliable jet airplane imaginable, with parts that would not fail in one billion hours of flight time under the most difficult weather conditions imaginable on Earth—and then let it be piloted by a drug addict high on painkillers.

The problem is that the whole flight system includes much more than just the reliability of the plane itself. Just because we built-in safety margins in one area does not mean the system will not fail. This illustrates not so much a failure of the model itself, but a common mistake in the way the model is applied.

* * *

This brings us to a final issue with the margin of safety model—naïve extrapolation of past data. Let's look at a common insurance scenario to illustrate this one.

Suppose we have a 100-year-old reinsurance company – PropCo – which reinsures major primary insurers in the event of property damage in California caused by a catastrophe – most worrying being an earthquake and its aftershocks. Throughout its entire (long) history, PropCo had never experienced a yearly loss on this sort of coverage worse than \$1 billion. Most years saw no loss worse than \$250 million, and in fact, many years had no losses at all – giving them comfortable profit margins.

Thinking like engineers, the directors of PropCo insisted that the company have such a strong financial position so that they could safely cover a loss twice as bad as anything ever encountered. Given their historical losses, the directors believed this extra capital would give PropCo a comfortable “margin of safety” against the worst case. Right?

However, our directors missed a few crucial details. The \$1 billion loss, the insurer's worst, had been incurred in the year 1994 during the Northridge earthquake. Since then, the building density of Californian cities had increased significantly, and due to ongoing budget issues and spreading fraud, strict building codes had not been enforced. Considerable inflation in the period since 1994 also ensured that losses per damaged square foot would be far higher than ever faced previously.

With these conditions present, let's propose that California is hit with an earthquake reading 7.0 on the Richter scale, with an epicenter 10 miles outside of downtown LA. PropCo faces a bill of \$5 billion – not twice as bad, but five times as bad as it had ever faced. In this case, PropCo fails.

This illustration (which recurs every so often in the insurance field) shows the limitation of naïvely assuming a margin of safety is presently based on misleading or incomplete past data.

* * *

The margin of safety is an important component of some decisions and life. You can think of it as a reservoir to absorb errors or poor luck. Size matters. At least, in this case, bigger is better. And if you need a calculator to figure out how much room you have, you're doing something wrong.

61. An Introduction to Complex Adaptive Systems

Let's explore the concept of the Complex Adaptive Systems and see how this model might apply in various walks of life.

To illustrate what a complex adaptive system is, and just as importantly, what it is not, let's take the example of a "driving system" – or as we usually refer to it, a car. (I have cribbed some parts of this example from the excellent book by John Miller and Scott Page.)

The interior of a car, at first glance is *complicated*. There are seats, belts, buttons, levers, knobs, a wheel, etc. Removing the passenger car seats would make this system *less* complicated. However, the system would remain essentially functional. Thus, we would not call the car interior *complex*.

The mechanical workings of a car, however, *are* complex. The system has interdependent components that must all simultaneously serve their function in order for the system to work. The higher-order function, driving, derives from the interaction of the parts in a very specific way.

Let's say instead of the passenger seats, we remove the timing belt. Unlike the seats, the timing belt is a necessary node for the system to function properly. Our "driving system" is now useless. The system has complexities, but they are not what we would call *adaptive*. To understand complex adaptive systems, let's put hundreds of "driving systems" on the same road, each with the goal of reaching their destination within an expected amount of time. We call this traffic. Traffic is a complex system in which its inhabitants *adapt* to each other's actions. Let's see it in action.

On a popular route into a major city, we observe a car in flames on the side of the road, with firefighters working to put out the fire. Naturally, cars will slow to observe the wreck. As the first cars slow, the cars behind them slow in turn. The cars behind them must slow as well. With everyone becoming increasingly agitated, we've got a traffic jam. The jam emerges from the interaction of the parts of the system.

With the traffic jam formed, potential entrants to the jam—let's call them Group #2—get on their smartphones and learn that there is an accident ahead which may take hours to clear. Upon learning of the accident, they predictably begin to adapt by finding another route.

Suppose there is only one alternate route into the city. What happens now? The alternate route forms a second jam! (I'm stressed out just writing about this.)

Now let's introduce a *third* group of participants, which must choose between jams.

Predicting the actions of this third group is very hard to do. Perhaps so many people in group #2 have altered their route that the second jam is worse than the first, causing the majority of the third group to choose jam #1. Perhaps, anticipating that others will follow that same line of reasoning, they instead choose jam #2. Perhaps they stay at home!

What we see here are the emergent properties of a complex adaptive system called traffic. By the time we hit this third layer of participants, predicting the behavior of the system has become extremely difficult, if not impossible.

The key element to complex adaptive systems is the social element. The belts and pulleys inside a car do not communicate with one another and adapt their behavior to the behavior of the other parts in an infinite loop. *Drivers*, on the other hand, do exactly that.

Where else do we see this phenomenon? The stock market is a great example. Instead of describing it myself, let's use the words of John Maynard Keynes, who brilliantly related the nature of the market's complex adaptive parts to that of a beauty contest in chapter 12 of *The General Theory*.

Or, to change the metaphor slightly, professional investment may be likened to those newspaper competitions in which the competitors have to pick out the six prettiest faces from a hundred photographs, the prize being awarded to the competitor whose choice

most nearly corresponds to the average preferences of the competitors as a whole; so that each competitor has to pick, not those faces which he himself finds prettiest, but those which he thinks likeliest to catch the fancy of the other competitors, all of whom are looking at the problem from the same point of view. It is not a case of choosing those which, to the best of one's judgment, are really the prettiest, nor even those which average opinion genuinely thinks the prettiest. We have reached the third degree where we devote our intelligences to anticipating what average opinion expects the average opinion to be. And there are some, I believe, who practice the fourth, fifth and higher degrees.

Like traffic, the complex, adaptive nature of the market is very clear. The participants in the market are interacting with one another constantly and *adapting their behavior* to what they know about others' behavior. Stock prices jiggle all day long in this fashion.

Forecasting outcomes in this system is extremely challenging.

To illustrate, suppose that a very skilled, influential, and perhaps lucky, market forecaster successfully calls a market crash. (There were a few in 2008, for example.) Five years later, he publicly calls for a second crash. Given his prescience in the prior crash, market participants might decide to sell their stocks rapidly, causing a crash for no other reason than the fact that it was predicted! Like traffic reports on the radio, the very act of observing and predicting has a crucial impact on the behavior of the system.

Thus, although we know that over the long term, stock prices roughly track the value of their underlying businesses, in the short run almost anything can occur due to the highly adaptive nature of market participants.

This understanding helps us understand some things that are *not* complex adaptive systems. Take the local weather. If the Doppler 3000 forecast on the local news predicts rain on Thursday, is the rain any less likely to occur? No. The act of predicting has not influenced the outcome. Although near-term weather is extremely complex, with many interacting parts leading to higher-order outcomes, it does have an element of predictability.

On the other hand, we might call the Earth's climate partially adaptive, due to the influence of human beings. (Have the cries of global warming and predictions of it worsening not begun affecting the very behavior causing the warming?)

Thus, behavioral dynamics indicate a key difference between weather and climate, and between systems that are simply complex and those that are also adaptive. Failure to use higher-order thinking when considering outcomes in complex adaptive systems is a common cause of overconfidence in prediction making.

62. Charlie Munger: Adding Mental Tools to Your Toolbox

In The Art of War, Sun Tzu said: “The general who wins a battle makes many calculations in his temple before the battle is fought.”

Those ‘calculations’ are the tools we have available to think better. One of the best questions you can ask is how we can make our mental processes work better.

Charlie Munger says that “developing the habit of mastering the multiple models which underlie reality is the best thing you can do.”

Those models are mental models.

Mental Models fall into a few categories, two of which are: (1) ones that help us simulate time (and predict the future) and better understand how the world works (e.g. understanding a useful idea autocatalysis), and (2) ones that help us better understand how our mental processes lead us astray (e.g., availability bias).

When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don’t line up with reality as we think something that isn’t true.

In Peter Bevelin’s Seeking Wisdom, he highlights Munger talking about autocatalysis:

If you get a certain kind of process going in chemistry, it speeds up on its own. So you get this marvellous boost in what you’re trying to do that runs on and on. Now, the laws of physics are such that it doesn’t run on forever. But it runs on for a goodly while. So you get a huge boost. You accomplish A – and, all of a sudden, you’re getting A + B + C for awhile.

He continues telling us how this idea can be applied:

Disney is an amazing example of autocatalysis ... They had those movies in the can. They owned the copyright. And just as Coke could prosper when refrigeration came, when the videocassette was invented, Disney didn’t have to invent anything or do anything except take the thing out of the can and stick it on the cassette.

This leads us to an interesting problem. The world is always changing, so which models should we prioritize learning?

How we prioritize our learning has implications beyond the day-to-day. Often we focus on things that change quickly. We chase the latest study, the latest findings, the most recent best-sellers. We do this to keep up-to-date with the latest-and-greatest.

Despite our intentions, learning in this way fails to account for cumulative knowledge.

Instead, we consume all of our time keeping up to date.

If we are prioritize learning, we should focus on things that change slowly.

The models that come from hard science and engineering are the most reliable models on this Earth. And engineering quality control – at least the guts of it that matters to you and me and people who are not professional engineers – is very much based on the elementary mathematics of Fermat and Pascal: It costs so much and you get so much less likelihood of it breaking if you spend this much...

And, of course, the engineering idea of a backup system is a very powerful idea. The engineering idea of breakpoints – that’s a very powerful model, too. The notion of a critical mass – that comes out of physics – is a very powerful model.

After we learn a model, we have to make it useful. We have to integrate it into our existing knowledge.

Our world is multi-dimensional and our problems are complicated. Most problems cannot be solved using one model alone. The more models we have, the better able we are to solve problems.

But if we don’t have the models, we become the proverbial man with a hammer. To the man with a hammer, everything looks like a nail. If you only have one model, you will fit whatever problem you face to the model you have. If you have more than one model; however, you can look at the problem from a variety of perspectives and increase the odds you come to a better solution.

“Since no single discipline has all the answers,” Peter Bevelin writes in Seeking Wisdom, “we need to understand and use the big ideas from all the important disciplines: Mathematics, physics, chemistry, engineering, biology, psychology, and rank and use them in order of reliability.”

Charles Munger illustrates the importance of this:

Suppose you want to be good at declarer play in contract bridge. Well, you know the contract – you know what you have to achieve. And you can count up the sure winners you have by laying down your high cards and your invincible trumps.

But if you’re a trick or two short, how are you going to get the other needed tricks? Well, there are only six or so different, standard methods: You’ve got long-suit establishment. You’ve got finesses. You’ve got throw-in plays. You’ve got cross-ruffs. You’ve got squeezes. And you’ve got various ways of misleading the defense into making errors. So it’s a very limited number of models. But if you only know one or two of those models, then you’re going to be a horse’s patoot in declarer play...

If you don’t have the full repertoire, I guarantee you that you’ll overutilize the limited repertoire you have — including use of models that are inappropriate just because they’re available to you in the limited stock you have in mind.

As for how we can use different ideas, Munger again shows the way ...

Have a full kit of tools ... go through them in your mind checklist-style.. you can never make any explanation that can be made in a more fundamental way in any other way than the most fundamental way. And you always take with full attribution to the most fundamental ideas that you are required to use. When you’re using physics, you say you’re using physics. When you’re using biology, you say you’re using biology.

But ideas alone are not enough. We need to understand how they interact and combine. This leads to lollapalooza effects.

You get lollapalooza effects when two, three or four forces are all operating in the same direction. And, frequently, you don’t get simple addition. It’s often like a critical mass in physics where you get a nuclear explosion if you get to a certain point of mass – and you don’t get anything much worth seeing if you don’t reach the mass.

Sometimes the forces just add like ordinary quantities and sometimes they combine on a break-point or critical-mass basis ... More commonly, the forces coming out of ... models are conflicting to some extent. And you get huge, miserable trade-offs ... So you [must] have the models and you [must] see the relatedness and the effects from the relatedness.

63. Overconfidence: How to Fail Spectacularly

© 2013 Behavior Gap

“What a Man wishes, he will also believe” – Demosthenes

Bias from overconfidence is a natural human state. All of us believe good things about ourselves and our skills.

In *Seeking Wisdom*, Peter Bevelin writes:

Most of us believe we are better performers, more honest and intelligent, have a better future, have a happier marriage, are less vulnerable than the average person, etc. But we can't all be better than average.

This inherent base rate of overconfidence is especially strong when projecting our beliefs about our future. Over-optimism is a form of overconfidence. Bevelin again:

We tend to Overestimate our ability to predict the future. People tend to put a higher probability on desired events than undesired events.

The bias from overconfidence is insidious because of how many factors can create and inflate it. Emotional, cognitive, and social factors all influence it. Emotional, as we see, because of the emotional pain of believing bad things about ourselves or our lives.

Emotional and Cognitive distortion that creates overconfidence is the dangerous and unavoidable accompaniment to any form of success.

Roger Lowenstein writes in *When Genius Failed*, “there is nothing like success to blind one to the possibility of failure.”

In *Seeking Wisdom*, Bevelin adds:

What tends to inflate the price that CEOs pay for acquisitions? Studies found evidence of infection through three sources of hubris: 1) overconfidence after recent success, 2) a sense of self-importance; the belief that a high salary compared to other senior ranking executives implies skill, and 3) the CEOs belief in their own press coverage. The media tend to glorify the CEO and over-attribute business success to the role of the CEO rather

than to other factors and people. This makes CEOs more likely to become both more overconfident about their abilities and more committed to the actions that made them media celebrities.

This isn't an effect confined to CEOs and large transactions. This feedback loop happens every day between employees and their managers. Or between students and professors, even peers and spouses.

Perhaps the most surprising, pervasive, and dangerous reinforcer of Overconfidence is the social incentives. Take a look at this example of social pressures on doctors from Kahneman in Thinking, Fast and Slow:

Generally, it is considered a weakness and a sign of vulnerability for clinicians to appear unsure. Confidence is valued over uncertainty and there is a prevailing censure against disclosing uncertainty to patients.

An unbiased appreciation of uncertainty is a cornerstone of rationality—but that is not what people and organizations want. Extreme uncertainty is paralyzing under dangerous circumstances, and the admission that one is merely guessing is especially unacceptable when the stakes are high. Acting on pretended knowledge is often the preferred solution. And what about those who don't succumb to this social pressure to let the Overconfidence bias run wild?

Kahneman writes, "Experts who acknowledge the full extent of their ignorance may expect to be replaced by more confident competitors, who are better able to gain the trust of the clients."

It's important to structure environments that allow for uncertainty, or the system will reward the most overconfident, not the most rational, of the decision-makers.

Making perfect forecasts isn't the goal — self-awareness is, in the form of wide confidence intervals. Kahneman, again in Thinking, Fast and Slow, writes:

For a number of years, professors at Duke University conducted a survey in which the chief financial officers of large corporations estimated the results of the S&P index over the following year. The Duke scholars collected 11,600 such forecasts and examined their accuracy. The conclusion was straightforward: financial officers of large corporations had no clue about the short-term future of the stock market; the correlation between their estimates and the true value was slightly less than zero! When they said the market would go down, it was slightly more likely than not that it would go up. these findings are not surprising. The truly bad news is that the CFOs did not appear to know that their forecasts were worthless.

You don't have to be right. You just have to know that you're not very likely to be right.

As always, with the lollapalooza effect of overlapping, combining, and compounding psychological effects, this one has powerful partners in some of our other mental models. Overconfidence bias is often caused or exacerbated by: doubt-avoidance, inconsistency-avoidance, incentives, denial, believing-first-and-doubting-later, and the endowment effect. Restraining Overconfidence

One way to restrain our tendency toward overconfidence is to habitually position ourselves in such a way that renders a prediction of the future unnecessary.

You might not know with certainty when the 100-year flood is coming, but you do know with certainty it will come. And that means you should leave yourself positioned accordingly.

The purpose of positioning is to make prediction unnecessary. You are prepared, or you are not. The argument for not preparing is one of efficiency. It's more efficient to only prepare when you need to. Being prepared all the time carries a cost.

Overconfidence lulls you into a false sense of security about the future and ensures your position is weakest at the very moment you need it to be strongest. When the storm comes, it won't give you a warning.

And in Seeking Wisdom, Bevelin reminds us that “Overconfidence can cause unreal expectations and make us more vulnerable to disappointment.” A few sentences later, he advises us to “focus on what can go wrong and the consequences.”

Build in some margin of safety in decisions. Know how you will handle things if they go wrong. Surprises occur in many unlikely ways. Ask: How can I be wrong? Who can tell me if I’m wrong?

64. Regression Toward the Mean: An Introduction with Examples

Regression to the mean is a common statistical phenomenon that can mislead us when we observe the world. Learning to recognize when regression to the mean is at play can help us avoid misinterpreting data and seeing patterns that don't exist.

It is important to minimize instances of bad judgment and address the weak spots in our reasoning. Learning about regression to the mean can help us.

Nobel prize-winning psychologist Daniel Kahneman wrote a book about biases that cloud our reasoning and distort our perception of reality. It turns out there is a whole set of logical errors that we commit because our intuition and brains do not deal well with simple statistics. One of the errors that he examines in Thinking Fast and Slow is the infamous regression toward the mean.

The notion of regression to the mean was first worked out by Sir Francis Galton. The rule goes that, in any series with complex phenomena that are dependent on many variables, where chance is involved, extreme outcomes tend to be followed by more moderate ones. In Seeking Wisdom, Peter Bevelin offers the example of John, who was dissatisfied with the performance of new employees so he put them into a skill-enhancing program where he measured the employees' skill:

Their scores are now higher than they were on the first test. John's conclusion: "The skill-enhancing program caused the improvement in skill." This isn't necessarily true. Their higher scores could be the result of regression to the mean. Since these individuals were measured as being on the low end of the scale of skill, they would have shown an improvement even if they hadn't taken the skill-enhancing program. And there could be many reasons for their earlier performance — stress, fatigue, sickness, distraction, etc. Their true ability perhaps hasn't changed.

Our performance always varies around some average true performance. Extreme performance tends to get less extreme the next time. Why? Testing measurements can never be exact. All measurements are made up of one true part and one random error part. When the measurements are extreme, they are likely to be partly caused by chance. Chance is likely to contribute less on the second time we measure performance.

If we switch from one way of doing something to another merely because we are unsuccessful, it's very likely that we do better the next time even if the new way of doing something is equal or worse.

This is one of the reasons it's dangerous to extrapolate from small sample sizes, as the data might not be representative of the distribution. It's also why James March argues that the longer someone stays in their job, "the less the probable difference between the observed record of performance and actual ability." Anything can happen in the short run, especially in any effort that involves a combination of skill and luck. (The ratio of skill to luck also impacts regression to the mean.)

"Regression to the mean is not a natural law. Merely a statistical tendency. And it may take a long time before it happens."

— Peter Bevelin

Regression to the Mean

The effects of regression to the mean can frequently be observed in sports, where the effect causes plenty of unjustified speculations.

In Thinking Fast and Slow, Kahneman recalls watching men's ski jump, a discipline where the final score is a combination of two separate jumps. Aware of the regression to the mean, Kahneman was startled to hear the commentator's predictions about the second jump. He writes:

Norway had a great first jump; he will be tense, hoping to protect his lead and will probably do worse” or “Sweden had a bad first jump and now he knows he has nothing to lose and will be relaxed, which should help him do better.

Kahneman points out that the commentator had noticed the regression to the mean and come up with a story for which there was no causal evidence (see narrative fallacy). This is not to say that his story could not be true. Maybe, if we measured the heart rates before each jump, we would see that they are more relaxed if the first jump was bad. However, that's not the point. The point is, regression to the mean happens when luck plays a role, as it did in the outcome of the first jump.

The lesson from sports applies to any activity where chance plays a role. We often attach explanations of our influence over a particular process to the progress or lack of it.

In reality, the science of performance is complex, situation dependent and often much of what we think is within our control is truly random.

In the case of ski jumps, a strong wind against the jumper will lead to even the best athlete showing mediocre results. Similarly, a strong wind and ski conditions in favor of a mediocre jumper may lead to a considerable, but a temporary bump in his results. These effects, however, will disappear once the conditions change and the results will regress back to normal.

This can have serious implications for coaching and performance tracking. The rules of regression suggest that when evaluating performance or hiring, we must rely on track records more than outcomes of specific situations. Otherwise, we are prone to be disappointed.

When Kahneman was giving a lecture to Israeli Air Force about the psychology of effective training, one of the officers shared his experience that extending praise to his subordinates led to worse performance, whereas scolding led to an improvement in subsequent efforts. As a consequence, he had grown to be generous with negative feedback and had become rather wary of giving too much praise.

Kahneman immediately spotted that it was regression to the mean at work. He illustrated the misconception by a simple exercise you may want to try yourself. He drew a circle on a blackboard and then asked the officers one by one to throw a piece of chalk at the center of the circle with their backs facing the blackboard. He then repeated the experiment and recorded each officer's performance in the first and second trial.

Naturally, those that did incredibly well on the first try tended to do worse on their second try and vice versa. The fallacy immediately became clear: the change in performance occurs naturally. That again is not to say that feedback does not matter at all – maybe it does, but the officer had no evidence to conclude it did.

The Imperfect Correlation and Chance

At this point, you might be wondering why the regression to the mean happens and how we can make sure we are aware of it when it occurs.

In order to understand regression to the mean, we must first understand correlation.

The correlation coefficient between two measures which varies between -1 and 1, is a measure of the relative weight of the factors they share. For example, two phenomena with few factors shared, such as bottled water consumption versus suicide rate, should have a correlation coefficient of close to 0. That is to say, if we looked at all countries in the world and plotted suicide rates of a specific year against per capita consumption of bottled water, the plot would show no pattern at all.

No Correlation

On the contrary, there are measures which are solely dependent on the same factor. A good example of this is temperature. The only factor determining temperature – velocity of molecules — is shared by all scales, hence each degree in Celsius will have exactly one corresponding value in Fahrenheit. Therefore temperature in Celsius and Fahrenheit will have a correlation coefficient of 1 and the plot will be a straight line.

Perfect Correlation

There are few if any phenomena in human sciences that have a correlation coefficient of 1. There are, however, plenty where the association is weak to moderate and there is some explanatory power between the two phenomena. Consider the correlation between height and weight, which would land somewhere between 0 and 1. While virtually every three-year-old will be lighter and shorter than every grown man, not all grown men or three-year-olds of the same height will weigh the same.

Weak to Moderate Correlation

This variation and the corresponding lower degree of correlation implies that, while height is generally speaking a good predictor, there clearly are factors other than the height at play. When the correlation of two measures is less than perfect, we must watch out for the effects of regression to the mean.

Kahneman observed a general rule: Whenever the correlation between two scores is imperfect, there will be regression to the mean.

This at first might seem confusing and not very intuitive, but the degree of regression to the mean is directly related to the degree of correlation of the variables. This effect can be illustrated with a simple example.

Assume you are at a party and ask why it is that highly intelligent women tend to marry men who are less intelligent than they are. Most people, even those with some training in statistics, will quickly jump in with a variety of causal explanations ranging from avoidance of competition to the fears of loneliness that these females face. A topic of such controversy is likely to stir up a great debate.

Now, what if we asked why the correlation between the intelligence scores of spouses is less than perfect? This question is hardly as interesting and there is little to guess – we all know this to be true. The paradox lies in the fact that the two questions happen to be algebraically equivalent. Kahneman explains:

[...] If the correlation between the intelligence of spouses is less than perfect (and if men and women on average do not differ in intelligence), then it is a mathematical inevitability that highly intelligent women will be married to husbands who are on average less intelligent than they are (and vice versa, of course). The observed regression to the mean cannot be more interesting or more explainable than the imperfect correlation.

Assuming that correlation is imperfect, the chances of two partners representing the top 1% in terms of any characteristic is far smaller than one partner representing the top 1% and the other – the bottom 99%.

The Cause, Effect, and Treatment

We should be especially wary of the regression to the mean phenomenon when trying to establish causality between two factors. Whenever correlation is imperfect, the best will always appear to get worse and the worst will appear to get better over time, regardless of any additional treatment. This is something that the general media and sometimes even trained scientists fail to recognize.

Consider the example Kahneman gives:

Depressed children treated with an energy drink improve significantly over a three-month period. I made up this newspaper headline, but the fact it reports is true: if you treated a group of depressed children for some time with an energy drink, they would show a clinically significant improvement. It is also the case that depressed children who spend some time standing on their head or hug a cat for twenty minutes a day will also show improvement.

Whenever coming across such headlines it is very tempting to jump to the conclusion that energy drinks, standing on the head or hugging cats are all perfectly viable cures for depression. These cases, however, once again embody the regression to the mean:

Depressed children are an extreme group, they are more depressed than most other children—and extreme groups regress to the mean over time. The correlation between depression scores on successive occasions of testing is less than perfect, so there will be regression to the mean: depressed children will get somewhat better over time even if they hug no cats and drink no Red Bull.

We often mistakenly attribute a specific policy or treatment as the cause of an effect, when the change in the extreme groups would have happened anyway. This presents a fundamental problem: how can we know if the effects are real or simply due to variability?

Luckily there is a way to tell between a real improvement and regression to the mean. That is the introduction of the so-called control group, which is expected to improve by regression alone. The aim of the research is to determine whether the treated group improve more than regression can explain.

In real life situations with the performance of specific individuals or teams, where the only real benchmark is the past performance and no control group can be introduced, the effects of regression can be difficult if not impossible to disentangle. We can compare against industry average, peers in the cohort group or historical rates of improvement, but none of these are perfect measures.

Luckily awareness of the regression to the mean phenomenon itself is already a great first step towards a more careful approach to understanding luck and performance.

If there is anything to be learned from the regression to the mean it is the importance of track records rather than relying on one-time success stories. I hope that the next time you come across an extreme quality in part governed by chance you will realize that the effects are likely to regress over time and will adjust your expectations accordingly.

65. Second-Order Thinking: What Smart People Use to Outperform

Understanding how to think things through – to push your mind past the first step – can help you solve problems, avoid problems, and take better actions.

The best way to examine the long-term consequences of our decisions is to think things through. This is called use second-order thinking.

It's often easier to identify when people don't adequately consider the second and subsequent-order impacts. For example, consider a country that, wanting to inspire regime change in another country, funds and provides weapons to a group of "moderate rebels." Only it turns out that those moderate rebels will become powerful and then go to war with the sponsoring country for decades. Whoops.

Failing to consider second- and third-order consequences is the cause of a lot of painfully bad decisions, and it is especially deadly when the first inferior option confirms your own biases. Never seize on the first available option, no matter how good it seems, before you've asked questions and explored.

Ray Dalio

The ability to think through problems to the second, third, and nth order—or what we will call second-order thinking for short—is a powerful thinking tool that not only solves problems but avoids them.

Second-Order Thinking

In his book, *The Most Important Thing*, Howard Marks explains the concept of second-order thinking, which he calls second-level thinking.

First-level thinking is simplistic and superficial, and just about everyone can do it (a bad sign for anything involving an attempt at superiority). All the first-level thinker needs is an opinion about the future, as in "The outlook for the company is favorable, meaning the stock will go up." Second-level thinking is deep, complex and convoluted.

First-order thinking is fast and easy. It happens when we look for something that only solves the immediate problem without considering the consequences. For example, you can think of this as I'm hungry, so let's eat a chocolate bar.

Second-order thinking is more deliberate. It is thinking in terms of interactions and time, understanding that despite our intentions our interventions often cause harm. Second order thinkers ask themselves the question "And then what?" This means thinking about the consequences of repeatedly eating a chocolate bar when you are hungry and using that to inform your decision. If you do this you're more likely to eat something healthy.

First-level thinking looks similar. Everyone reaches the same conclusions. This is where things get interesting. The road to out-thinking people can't come from first-order thinking. It must come from second-order thinking. Extraordinary performance comes from seeing things that other people can't see.

Improving Your Ability To Think

Here are some ways to put second-order thinking into practice today.

1. Always ask yourself, "And then what?"
2. Think across time — What do the consequences look like in 10 minutes? 10 months? 10 Years?
3. Create templates like the second image above with 1st, 2nd, and 3rd order consequences. Identify your decision, think it through, and write down the consequences. If you review these regularly you'll be able to help calibrate your thinking.
4. If you're using this to think about business decisions, ask yourself how important parts of the ecosystem are likely to respond. How will employees deal with this? What will my competitors likely do? What about my suppliers? What about the regulators? Often, the answer will be little to no impact, but you want to understand the immediate and second-order consequences before you make the decision.

A lot of extraordinary things in life are the result of things that are first-order negative, second order positive. So just because things look like they have no immediate payoff, doesn't mean that's the case. All it means is that you'll have less competition if the second and third order consequences are positive because everyone who thinks at the first order won't think things through.

Second-order thinking takes a lot of work. It's not easy to think in terms of systems, interactions, and time. However, doing so is a smart way to separate yourself from the masses.

66. Mental Model: Misconceptions of Chance

We expect the immediate outcome of events to represent the broader outcomes expected from a large number of trials. We believe that chance events will immediately self-correct and that small sample sizes are representative of the populations from which they are drawn. All of these beliefs lead us astray.

Our understanding of the world around us is imperfect, and when dealing with chance, our brains tend to come up with ways to cope with the unpredictable nature of our world.

"We tend," writes Peter Bevelin in *Seeking Wisdom*, "to believe that the probability of an independent event is lowered when it has happened recently or that the probability is increased when it hasn't happened recently."

In short, we believe an outcome is due, and that chance will self-correct. The problem with this view is that nature doesn't have a sense of fairness or memory. We only fool ourselves when we mistakenly believe that independent events offer influence or meaningful predictive power over future events.

Furthermore, we also mistakenly believe that we can control chance events. This applies to risky or uncertain events.

Chance events, coupled with positive reinforcement or negative reinforcement, can be a dangerous thing. Sometimes we become optimistic and think our luck will change, and sometimes we become overly pessimistic or risk-averse.

How do you know if you're dealing with chance? A good heuristic is to ask yourself if you can lose on purpose. If you can't, you're likely far into the chance side of the skill vs. luck continuum. No matter how hard you practice, the probability of chance events won't change.

"We tend," writes Nassim Taleb in *The Black Swan*, "to underestimate the role of luck in life in general (and) overestimate it in games of chance."

We are only discussing independent events. If events are dependent, where the outcome depends on the outcome of some other event, all bets are off.

Misconceptions of Chance

Daniel Kahneman coined the term misconceptions of chance to describe the phenomenon of people extrapolating large-scale patterns to samples of a much smaller size. Our trouble navigating the sometimes counterintuitive laws of probability, randomness, and statistics leads to misconceptions of chance.

Kahneman found that "people expect that a sequence of events generated by a random process will represent the essential characteristics of that process even when the sequence is short."

In the paper, Belief in the Law of Small Numbers, Kahneman and Tversky reflect on the results of an experiment, where subjects were instructed to generate a random sequence of hypothetical tosses of a fair coin.

They [the subjects] produce sequences where the proportion of heads in any short segment stays far closer to .50 than the laws of chance would predict. Thus, each segment of the response sequence is highly representative of the "fairness" of the coin.

Unsurprisingly, the same nature of errors occurred when the subjects, instead of being asked to generate sequences themselves, were simply asked to distinguish between random and human-generated sequences. It turns out that when considering tosses of a coin for heads or tails people regard the sequence H-T-H-T-T-H to be more likely than the sequence H-H-H-T-H-T, which does not appear random, and also more likely than the sequence H-H-H-H-T-H. In reality, each one of those sequences has the exact same probability of occurring. This is a misconception of chance.

The aspect that most of us find so hard to grasp about this case is that any pattern of the same length is just as likely to occur in a random sequence. For example, the odds of getting 5 tails in a row are 0.03125 or simply stated 0.5 (the odds of a specific outcome at each trial) to the power of 5 (number of trials).

The same probability rule applies for getting the specific sequences of HHTHT or THTHT – where each sequence is obtained by once again taking 0.5 (the odds of a specific outcome at each trial) to the power of 5 (number of trials), which equals 0.03125.

This probability is true for sequences – but it implies no relation between the odds of a specific outcome at each trial and the representation of the true proportion within these short sequences.

Yet it's still surprising. This is because people expect that the single event odds will be reflected not only in the proportion of events as a whole but also in the specific short sequences we encounter. But this is not the case. A perfectly alternating sequence is just as extraordinary as a sequence with all tails or all heads.

In comparison, “a locally representative sequence,” Kahneman writes, in *Thinking, Fast and Slow*, “deviates systematically from chance expectation: it contains too many alternations and too few runs. Another consequence of the belief in local representativeness is the well-known gambler’s fallacy.”

Gambler’s Fallacy

There is a specific variation of the misconceptions of chance that Kahneman calls the Gambler’s fallacy (elsewhere also called the Monte Carlo fallacy).

The gambler’s fallacy implies that when we come across a local imbalance, we expect that the future events will smoothen it out. We will act as if every segment of the random sequence must reflect the true proportion and, if the sequence has deviated from the population proportion, we expect the imbalance to soon be corrected.

Kahneman explains that this is unreasonable – coins, unlike people, have no sense of equality and proportion:

The heart of the gambler’s fallacy is a misconception of the fairness of the laws of chance. The gambler feels that the fairness of the coin entitles him to expect that any deviation in one direction will soon be cancelled by a corresponding deviation in the other. Even the fairest of coins, however, given the limitations of its memory and moral sense, cannot be as fair as the gambler expects it to be.

He illustrates this with an example of the roulette wheel, and our expectations when a reasonably long sequence of repetition occurs.

After observing a long run of red on the roulette wheel, most people erroneously believe that black is now due, presumably because the occurrence of black will result in a more representative sequence than the occurrence of an additional red.

In reality, of course, roulette is a random, non-evolving process, in which the chance of getting a red or a black will never depend on the past sequence. The probabilities restore after each run, yet we still seem to take the past moves into account.

Contrary to our expectations, the universe does not keep an accounting of a random process, so streaks are not necessarily tilted towards the true proportion. Your chance of getting a red after a series of blacks will always be equal to that of getting another red as long as the wheel is fair.

The gambler’s fallacy need not to be committed inside the casino only. Many of us commit it frequently by thinking that a small, random sample will tend to correct itself.

For example, assume that the average IQ at a specific country is known to be 100. And for the purposes of assessing intelligence at a specific district, we draw a random sample of 50 persons. The first person in our sample happens to have an IQ of 150. What would you expect the mean IQ to be for the whole sample?

The correct answer is $(100 \times 49 + 150 \times 1) / 50 = 101$. Yet without knowing the correct answer, it is tempting to say it is still 100 – the same as in the country as a whole.

According to Kahneman and Tversky, such expectation could only be justified by the belief that a random process is self-correcting and that the sample variation is always proportional. They explain:

Idioms such as “errors cancel each other out” reflect the image of an active self-correcting process. Some familiar processes in nature obey such laws: a deviation from a stable equilibrium produces a force that restores the equilibrium.

Indeed, this may be true in thermodynamics, chemistry, and arguably also economics. These, however, are false analogies. It is important to realize that the laws governed by chance are not guided by principles of equilibrium, and the number of random outcomes in a sequence does not have a common balance.

“Chance,” Kahneman writes in *Thinking, Fast and Slow*, “is commonly viewed as a self-correcting process in which a deviation in one direction induces a deviation in the opposite direction to restore the equilibrium. In fact, deviations are not “corrected” as a chance process unfolds, they are merely diluted.”

The Law of Small Numbers

Misconceptions of chance are not limited to gambling. In fact, most of us fall for them all the time because we intuitively believe (and there is a whole best-seller section at the bookstore to prove) that inferences drawn from small sample sizes are highly representative of the populations from which they are drawn.

By illustrating people’s expectations of random heads and tails sequences, we already established that we have preconceived notions of what randomness looks like. This, coupled with the unfortunate tendency to believe in the self-correcting process in a random sample, generates expectations about sample characteristics and representativeness, which are not necessarily true. The expectation that the patterns and characteristics within a small sample will be representative of the population as a whole is called the law of small numbers.

Consider the sequence:

1, 2, 3, __, __, __

What do you think are the next three digits?

The task almost seems laughable because the pattern is so familiar and obvious – 4,5,6. However, there is an endless variation of different algorithms that would still fit the first three numbers, such as the Fibonacci sequence (5, 8, 13), a repeated sequence (1,2,3), a random sequence (5,8,2) and many others. Truth is, in this case, there simply is not enough information to say what the rules governing this specific sequence are with any reliability.

The same rule applies to sampling problems – sometimes, we feel we have gathered enough data to tell a real pattern from an illusion. Let me illustrate this fallacy with yet another example.

Imagine that you face a tough decision between investing in the development of two different product opportunities. Let’s call them Product A or Product B. You are interested in which product would appeal to the majority of the market, so you decide to conduct customer interviews. Out of the first five pilot interviews, four customers show a preference for Product A. While the sample size is quite small, given the time pressure involved, many of us would already have some confidence in concluding that the majority of customers would prefer Product A.

However, a quick statistical test will tell you that the probability of a result just as extreme is, in fact 3/8, assuming that there is no preference among customers at all. This in simple terms, means that if customers had no preference between Products A and B, you would still expect 3 customer samples out of 8 to have four customers vouching for Product A. Basically, a study of such size has little to no predictive validity – these results could easily be obtained from a population with no preference for one or the other product. This, of course, does not mean that talking to customers is of no value. Quite the contrary – the

more random cases we examine, the more reliable and accurate the results of the true proportion will be. If we want absolute certainty, we must be prepared for a lot of work. There will always be cases where a guesstimate based on a small sample will be enough because we have other critical information guiding the decision-making process or we simply do not need a high degree of confidence. Yet rather than assuming that the samples we come across are always perfectly representative, we must treat random selection with the suspicion it deserves. Accepting the role imperfect information and randomness play in our lives and being actively aware of what we don't know already makes us better decision-makers.

67. Bias from Association: Why We Shoot the Messenger

We automatically connect a stimulus (thing/person) with pain (fear) or pleasure (hope). As pleasure seeking animals, we seek out positive associations and attempt to remove negative ones. This happens when we experience the positive or negative consequences of a stimulus. The more vivid the event, the easier it is to remember. Brands (including people) attempt to influence our behavior by associating with positive things.

Bias from Association

Our life and memory revolve around associations. The smell of a good lunch makes our stomach growl, the songs we hear remind us about the special times that we have had and horror movies leave us with goosebumps.

These natural, uncontrolled responses upon a specific signal are examples of classical conditioning. Classical conditioning, or in simple terms — learning by association, was discovered by a Russian scientist Ivan Petrovich Pavlov. Pavlov was a physiologist whose work on digestion in dogs won him a Nobel Prize in 1904.

In the course of his work in physiology, Pavlov made an accidental observation that dogs started salivating even before their food was presented to them.

With repeated testing, he noticed that the dogs began to salivate in anticipation of a specific signal, such as the footsteps of their feeder or if conditioned that way, even after the sound of a tone.

Pavlov's genius lay in his ability to understand the implications of his discovery. He knew that dogs have a natural reflex of salivating to food but not to footsteps or tones. He was on to something. Pavlov realized that, if coupling the two signals together induced the same reactive response in dogs, then other physical reactions may be inducible via similar associations.

In effect, with *Pavlovian association*, we respond to a stimulus because we anticipate what comes next: the reality that would make our response correct.

Now things get interesting.

Rules of Conditioning

Suppose we want to condition a dog to salivate to a tone. If we sound the tone without having taught the dog to specifically respond, the ears of the dog might move, but the dog will not salivate. The tone is just a neutral stimulus, at this point. On the other hand, food for the dog is an unconditioned stimulus, because it always makes the dog salivate.

If we now pair the arrival of food and the sound of the tone, we elicit a learning trial for the dog. After several such trials, the association develops and is strong enough to make the dog salivate even though there is no food. The tone, at this point, has become a conditioned stimulus. This is learned hope. Learned fear is more easily acquired.

The speed and degree to which the dog learns to display the response will depend on several factors.

The best results come when the conditioned stimulus is paired with the unconditioned one several times. This develops a strong association. It takes time for our brains to detect specific patterns.

Classical conditioning involves automatic or reflexive responses and not voluntary behavior.

There are also cases to which this principle does not apply. When we undergo high impact events, such as a car crash, robbery, or firing from a job, a single event will be enough to create a strong association.

Why We Shoot The Messenger

One of our goals should be to understand how the world works. A necessary condition for this is understanding our problems. However, sometimes people are afraid to tell us problems.

This is also known as The Pavlovian Messenger Syndrome.

The original messenger wasn't shot, he was beheaded. In Plutarch's Lives, we find: *The first messenger, that gave notice of Lucullus' coming was so far from pleasing Tigranes that, he had his head cut off for his pains; and no man dared to bring further information. Without any intelligence at all, Tigranes sat while war was already blazing around him, giving ear only to those who flattered him.*

The number of times that happens in an organization is countless. A related sentiment exists in Antigone by Sophocles as "No one loves the messenger who brings bad news." In A Lesson on Worldly Wisdom, Charlie Munger said:

If people tell you what you really don't want to hear — what's unpleasant — there's an almost automatic reaction of antipathy. You have to train yourself out of it. It isn't foredestined that you have to be this way. But you will tend to be this way if you don't think about it.

In Antony and Cleopatra, when told Antony has married another, Cleopatra threatens to treat the messenger poorly, eliciting the response "Gracious madam, I that do bring the news made not the match."

And the advice "Don't shoot the messenger" appears in Henry IV, Part 2.

If you happen to be the messenger, it might be best to deliver the news first via and appear in person later to minimize the negative feelings towards you.

If, on the other hand, you're the receiver of bad news, it's best to follow the advice of Warren Buffett, who comments on being informed of bad news:

We only give a couple of instructions to people when they go to work for us: One is to think like an owner. And the second is to tell us bad news immediately — because good news takes care of itself. We can take bad news, but we don't like it late.

Pavlov showed that sequence matters: the association is most clear to us when the conditioned stimulus appears first and remains after the unconditioned stimulus is introduced.

Unsurprisingly, our learning responses become weaker if the two stimuli are introduced at the same time and are even slower if they are presented in reverse (unconditioned then conditioned stimulus) order.

Attraction and Repulsion

There's no doubt that classical conditioning influences what attracts us and even arouses us. Most of us will recognize that images and videos of kittens will make our hearts softer and perfume or a look from our partner can make our hearts beat faster.

Charlie Munger explains the case of building Coca-Cola, whose marketing and product strategy is built on strong foundations of conditioning.

Munger walks us through the creation of the brand by using conditioned reflexes:

The neural system of Pavlov's dog causes it to salivate at the bell it can't eat. And the brain of man yearns for the type of beverage held by the pretty woman he can't have. And so, Glotz, we must use every sort of decent, honorable Pavlovian conditioning we can think of. For as long as we are in business, our beverage and its promotion must be associated in consumer minds with all other things consumers like or admire.

By repeatedly pairing a product or brand with a favorable impression, we can turn it into a conditioned stimulus that makes us buy.

This goes even beyond advertising — conditioned reflexes are also encompassed in Coca Cola's name. Munger continues:

Considering Pavlovian effects, we will have wisely chosen the exotic and expensive-sounding name "Coca-Cola," instead of a pedestrian name like "Glotz's Sugared, Caffeinated Water."

And even texture and taste:

And we will carbonate our water, making our product seem like champagne, or some other expensive beverage, while also making its flavor better and imitation harder to arrange for competing products.

Combining these and other clever, non-Pavlovian techniques lead to what Charlie Munger calls the lollapalooza effect, causing so many consumers to buy and making Coca-Cola an excellent business for over a century.

While Coca-Cola has some of its advantages rooted in positive Pavlovian association, there are cases when associations do no good. In childhood, many of us were afraid of doctors or dentists, because we quickly learned to associate these visits with pain.

While we may have lost our fear of dentists, by now many of us experience similarly unpleasant feelings when opening a letter from the police or anticipating a negative performance review.

Constructive criticism can be one of life's great gifts and an engine for improvement, however, before we can benefit from it, we must be prepared that some of it will hurt. If we are not at least implicitly aware of the conditioning phenomena and have people telling us what we don't want to hear, we may develop a certain disliking to those delivering the news.

The number of people in leadership positions unable to detach the information from the messenger can be truly surprising. In *The Psychology of Human Misjudgement*, Munger tells about the ex-CEO of CBS, William Paley, who had a blind spot for ideas that did not align with his views.

Television was dominated by one network-CBS-in its early days. And Paley was a god. But he didn't like to hear what he didn't like to hear, and people soon learned that. So they told Paley only what he liked to hear. Therefore, he was soon living in a little cocoon of unreality and everything else was corrupt although it was a great business.

In the case of Paley, his inability to take criticism and recognize incentives was soon noticed by those around him, and it resulted in sub-optimal outcomes.

... If you take all the acquisitions that CBS made under Paley after the acquisition of the network itself, with all his dumb advisors-his investment bankers, management consultants, and so forth, who were getting paid very handsomely-it was absolutely terrible.

Paley is by no means the only example of such dysfunction in the high ranks of business. In fact, the higher up you are in an organization, the more people fear telling you the truth. Providing sycophants with positive reinforcement will only encourage this behavior and ensure you're insulated from reality.

To make matters worse, as we move up in seniority, we also tend to become more confident about our own judgments being correct. This is a dangerous tendency, but we need not be bound by it.

We can train ourselves out of it with reflection and effort.

Escaping Associations

No doubt that learning via associations is crucial for our survival — it alerts us about the arrival of an important event and gives us time to prepare for the appropriate response. Sometimes, however, learned associations do not serve us and our relationships well. We find that we have become subject to negative responses in others or recognize unreasonable responses in ourselves.

Awareness and understanding may serve as good first steps. Yet, even when taken together, they may not be sufficient to unlearn some of the more stubborn associations. In such cases, we may want to try several known techniques to desensitize them or reverse their negative effects.

One way to proceed is via habituation.

When we habituate someone, we blunt down their conditioned response by exposing them to the specific stimulus pairing continuously. After a while, they simply stop responding.

This loss of interest is a natural learning response that allows us to conserve energy for stimuli that are unfamiliar and therefore draw the attention of the mind.

Continuous exposure can yield results as powerful as becoming fully indifferent to stimuli as strong as violence and death.

In Man's Search For Meaning, Viktor Frankl, a holocaust survivor, tells about experiencing absolute desensitization to the most horrific events imaginable:

Disgust, horror and pity are emotions that our spectator [Frankl] could not really feel any more. The sufferers, the dying and the dead, became such commonplace sights to him after a few weeks of camp life that they could not move him any more.

Of course, habituation can also serve good motives, such as getting ourselves over fear, overcoming trauma, or harmonizing relationships by making each side less sensitive to the other side's vices. However, as powerful as habituation is, we must recognize its limitations.

If we want someone to respond differently rather than become indifferent, flooding them with stimuli will not help us achieve our aims.

Consider the case for teaching children – the last thing we would want is to make them indifferent to what we say. Therefore instead of habituation, we should employ another strategy.

A frequently used technique in coaching, exposure therapy, involves cutting back our criticism for a while and reintroducing it by gradually lowering the person's threshold for becoming defensive.

The key difference between exposure therapy and habituation lies in being subtle rather than blunt.

If we try to avoid forming negative associations and achieve behavioral change at the same time, we will always want the positive vs. negative feedback ratio to be in favor of the positive. This is why we so often provide feedback in a "sandwich," where a positive remark is followed by what must be improved and then finished with another positive remark.

Aversion therapy is the exact opposite of exposure therapy.

Aversion therapy aims to exchange a positive association with a negative one within a few high impact events. For example, some parents teach out a sweet tooth by forcing their children to consume an insurmountable amount of sweets in one sitting under their supervision.

While ethically questionable this idea is not completely unfounded.

If the experience is traumatic enough, the positive associations of, for example, a sugar high, will be replaced by the negative association of nausea and sickness.

This controversial technique was used in experiments with alcoholics. While effective in theory, it was known to yield only mixed results in practice, with patients often resorting back to past conditions over time.

This is also why there are gross and terrifying pictures on cigarette packages in many countries.

Overall, creating habits that last or permanently breaking them can be a tough mission to embark upon.

In the case of feedback, we may try to associate our presence with positive stimuli, which is why building great first impressions and appearing friendly matters.

Keep in Mind

When thinking about this bias it's important to keep in mind that: (1) people are neither good nor bad because we associate something positive or negative to them; (2) bad news should be sought immediately and your reaction to it will dictate how much of it you hear; (3) to end a certain behavior or habit you can create an association with a negative emotion.

68. Bias from Self-Interest — Self Deception and Denial to Reduce Pain or Increase Pleasure

Our desire to feel good about ourselves permeates everything we do. Wanting to maintain a positive self-image often leads us to adopt a biased image of the world. If we want to learn to align ourselves with the facts, we must stop denying reality and rationalizing our choices.

Our Self-Esteem

Our self-esteem can be a very important aspect of personal well-being, adjustment, and happiness. It has been reported that people with higher self-esteem are happier with their lives, have fewer interpersonal problems, achieve at a higher and more consistent level and give in less to peer pressure.

The strong motivation to preserve a positive and consistent self-image is more than evident in our lives.

We attribute success to our own abilities and failures to environmental factors and we continuously rate ourselves as better than average on any subjective measure – ethics, beauty, and ability to get along with others.

Look around – these positive illusions appear to be the rule rather than the exception in well-adjusted people.

However, sometimes life is harsh on us and gives few if any reasons for self-love.

We get fired, a relationship ends, and we end up making decisions that are not well aligned with our inner selves. And so we come up with ways to straighten our damaged self-image.

Under the influence of bias from self-interest, we may find ourselves drifting away from facts and spinning them to the point they become acceptable. While the tendency is mostly harmless and episodic, there are cases when it grows extreme.

The imperfect and confusing realities of our life can activate strong responses, which helps us preserve ourselves and our fragile self-images. Usually amplified by love, death or chemical dependency, strong self-serving bias may leave the person with little capacity to assess the situation objectively.

In his speech, *The Psychology of Human Misjudgment*, Charlie Munger reflects on the extreme tendencies that serious criminals display in Tolstoy's novels and beyond. Their defense mechanisms can be divided into two distinct types – they are either in denial of committing the crime at all or they think that the crime is justifiable in light of their hardships.

Munger coins the two cases *the Tolstoy effect*.

Avoiding Reality by Denying It

Denial occurs, when we encounter a serious thought about reality, but decide to ignore it. Imagine one day you notice a strange, dark spot on your skin. You feel a sudden sense of anxiety, but soon go on with your day and forget about it. Weeks later, it has not gone away and has slowly become darker and you eventually decide to take action and visit the doctor.

In such cases, small doses of denial might serve us well. We have time to absorb the information slowly and figure out the next steps for action, in case our darkest fears come true. However, once denial becomes a prolonged measure for coping with troubling matters, causing our problems to amplify, we are bound to suffer from consequences.

The consequences can be different. The mildest one is a simple inability to move on with our lives.

Charlie Munger was startled to see a case of persistent denial in a family friend:

This first really hit me between the eyes when a friend of our family had a super-athlete, super-student son who flew off a carrier in the north Atlantic and never came back, and his mother, who was a very sane woman, just never believed that he was dead.

The case made him realize that denial is often amplified by intense feelings of love and death. We're denying to avoid pain.

While denial of the death of someone close is usually harmless and understandable, it can become a significant problem, when we deny an issue that is detrimental to ourselves and others.

A good example of such issues are physical dependencies, such as alcoholism or drug addiction.

Munger advises staying away from any opportunity to slip into an addiction since the psychological effects are most damaging. The reality distortion that happens in the minds of drug addicts leads them to believe that they have remained in a respectable condition and with reasonable prospects even as their condition keeps deteriorating.

Rationalizing Our Choices

A less severe case of distortion, but no less foolish, is our tendency to rationalize the choices we have made.

Most of us have a positive concept of ourselves and we believe ourselves to be competent, moral and smart.

We can go to great lengths to preserve this self-image. No doubt we have all engaged in behaviors that are less than consistent with our inner self-image and then used phrases, such as "not telling the truth is not lying", "I didn't have the time" and "others are even worse" to justify our less than ideal actions.

This tendency in part can be explained by the engine that drives self-justification called cognitive dissonance. It is the state of tension that occurs, whenever we hold two opposing facts in our heads, such as "smoking is bad" and "I smoke two packs a day".

Dissonance bothers us under any circumstances, but it becomes particularly unbearable when our self-concept is threatened by it. After all, we spend our lives trying to lead lives that are consistent and meaningful. This drive "to save face" is so powerful that it often overrules and contradicts the pure effects of rewards and punishments as assumed by economic theory or observed in simple animal behavioral research.

The most obvious way to quiet dissonance is by quitting. However, a smoker that has tried to quit and failed can also quiet the other belief – namely that smoking is not all that bad. It is a simple and failure-free option that allows her to feel good about herself and requires hardly any effort. Having suspended our moral compass only once and found rationales for the bad, but fixable, choices gives us permission to repeat them in the future and continue the vicious cycle.

The Vicious Cycle of Self-Justification

Carol Tavris and Elliot Aronson in their book Mistakes Were Made (But Not by Me): Why We Justify Foolish Beliefs, Bad Decisions, and Hurtful Acts explain the vicious cycle of choices with an analogy of a pyramid.

Consider the case of two reasonably honest students at the beginning of the term. They face the temptation to cheat on an important test. One of them gives in and the other does not. How do you think they will feel about cheating a week later?

Most likely their initially torn opinions will have polarized in light of their initial choices. Now take this effect and amplify it over the term. By the time they are through with the term two things will have happened:

- 1) They will be very far from each other in their beliefs
- 2) They will be convinced that they have always felt strongly about the issue and their side of the argument

Just like those students, we are often at the top of the choice pyramid, facing a decision whose consequences are morally ambiguous. This first choice then starts a process of entrapment of action – justification – further action, which increases the intensity of our commitment

Over time our choices reinforce themselves and towards the bottom of the pyramid, we find ourselves rolling toward increasingly extreme views.

Consider the famous Stanley Milgram experiment, where two thirds of the 3,000 subjects administered a life threatening level of electric shock to another person. While this study is often used to illustrate our obedience to authority, it also demonstrates the effects of *self-justification*.

Simply imagine the scenario of someone asking you to do the favor inflicting 500V of potentially deadly and incredibly painful shock on another person for the sake of science. Chances are most of us would refuse it under any circumstances.

Now suppose the researcher tells you he is interested in effects of punishment on learning and you will have to inflict hardly noticeable electric impulses on another person. You are even encouraged to try the lower levels of 10V yourself to feel that the pain is hardly noticeable.

When you come along, suddenly the experimenter asks you to increase the shock to 20V, which seems like a small increase, so you agree without thinking much. Then the cascade continues – if you gave 20V shock, what is the harm in giving 30V? Suddenly you find yourself unable to draw the line, so you simply tag along with the instructions.

When people are asked in advance whether they would administer shock above 450V, nearly nobody believes they would. However, when facing the choice under pressing circumstances, two-thirds of them did!

The implications here are powerful – if we don't actively draw the line ourselves, our habits and circumstances will decide for us.

Making Smarter Choices

We will all do dumb things. We can't help it. We are wired that way. However, we are not doomed to live in denial or keep striving to justify our actions. We always have the choice to correct our tendencies, once we recognize them.

A better understanding of our minds serves as the first step towards breaking the self-justification habit. It takes time, self-reflection and willingness to become more mindful about our behavior and reasons for our behavior, but it is well worth the effort.

The authors of Mistakes Were Made (But not By Me) give an example of conservative William Safire, who wrote a column criticizing (then and current) American presidential candidate Hillary Clinton's efforts to conceal the identity of her health care task force. A few years later Dick Cheney, a Republican (conservative) candidate whom Safire admired, made a similar move to Clinton by insisting on keeping his energy task force secret. The alarm bell in Safire's head rang and he admits that the temptation to rationalize the occasion and apply double standards was enormous. However, he recognized the dissonance effects and ended up writing a similar column about Cheney.

We know that Safire's ability to spot his own dissonance and do the fair thing is rare.

People will bend over backward to reduce dissonance in a way that is favorable to them and their team. Resisting that urge is not easy to do, but it is much better than letting the

natural psychological tendencies cripple the integrity of our behaviors. There are ways to make fairness easier.

Making Things Easier

On the personal level, Charlie Munger suggests we should face two simple facts. Firstly, fixable, but unfixed bad performance is bad character and tends to create more of itself and cause more damage — a sort of Gresham's Law. And, secondly, in demanding places like athletic teams, excuses and bad behavior will not get us far.

On the institutional level, Munger advises building a fair, meritocratic, demanding culture plus personnel handling methods that build up morale. His second piece of advice is the severance of the worst offenders, when possible.

Munger expands on the second point by noting that it is not in any case possible to let go our children, but we must, therefore, try to fix them to our best ability. He gives a real life example of a child, who had the habit of taking candy from the stock of his father's employer with the excuse that he had intended to replace it later. The father said words that never left the child:

"Son, it would be better for you to simply take all you want and call yourself a thief every time you do it."

Turns out the child in this example was the dean of University of Southern California Business School, where Munger delivered the speech.

If we are effective, the lessons we teach our children will serve them well throughout their lives.

There is so much more to touch on with bias from self-interest, including its relation to hierarchy, how it distorts information, how it feeds our desire for self-preservation and scarcity, how it impacts group preservation, its relationship to terror etc.

69. The Map Is Not the Territory

The map-territory mental model is about understanding the difference between perceptions (the 'map') and the actual reality (the 'territory'). It's like having a map of a city: the map can help you navigate and understand the city, but it's not the same as walking the streets and experiencing it yourself. Roads close. Intersections get blocked. So, just like a map can be outdated or incomplete, our beliefs might not always match the real world exactly.

The map of reality is not reality. Even the best maps are imperfect. That's because they are reductions of what they represent. If a map were to represent the territory with perfect fidelity, it would no longer be a reduction and thus would no longer be useful to us. A map can also be a snapshot of a point in time, representing something that no longer exists. This is important to remember as we think through problems and make better decisions. The map appears to us more real than the land.

— D.H. Lawrence
The Relationship Between Map and Territory

In 1931, in New Orleans, Louisiana, mathematician Alfred Korzybski presented a paper on mathematical semantics. To the non-technical reader, most of the paper reads like an abstruse argument on the relationship of mathematics to human language and physical reality. Important stuff, certainly, but not necessarily immediately useful for the layperson. In his string of arguments on language structure, Korzybski introduced and popularized the idea that *the map is not the territory*. In other words, the description of the thing is not the thing itself. The model is not reality. The abstraction is not abstracted. *This* has enormous practical consequences.

In Korzybski's words:

A.) A map may have a structure similar or dissimilar to the structure of the territory.

B.) Two similar structures have similar 'logical' characteristics. Thus, if in a correct map, Dresden is given as between Paris and Warsaw, a similar relation is found in the actual territory.

C.) A map is not the actual territory.

D.) An ideal map would contain the map of the map, the map of the map of the map, etc., endlessly...We may call this characteristic self-reflexiveness.

Maps are necessary but flawed. (By maps, we mean any abstraction of reality, including descriptions, theories, models, etc.) The problem with a map is not simply that it is an abstraction; we need abstraction. A map with a scale of one mile to one mile would not have the problems that maps have, nor would it be helpful.

To solve this problem, the mind creates maps of reality to understand it. The only way we can process the complexity of reality is through abstraction. We might be able to see the world in 4k video, but we can't handle all the details. Our minds work to omit what isn't necessary.

Frequently, we don't understand our maps or their limits. In fact, we are so reliant on abstraction that we will frequently use an incorrect model simply because we feel *any* model is preferable to *no* model. (Reminding one of the drunk looking for his keys under the streetlight because "That's where the light is!")

Even the best and most useful maps suffer from limitations, and Korzybski gives us a few to explore: (A.) The map could be *incorrect* without us realizing it; (B.) The map is, by necessity, a *reduction* of the actual thing, a process in which you lose certain important information; and (C.) A map needs *interpretation*, a process that can cause major errors. (The only way to solve the last would be an endless chain of maps of maps, which he called self-reflexiveness.)

With the aid of modern psychology, we also see another issue: the human brain takes great leaps and shortcuts to make sense of its surroundings.

As Charlie Munger has pointed out, a good idea and the human mind act like the sperm and the egg — after the first good idea gets in, the door closes. This makes the map-territory problem a close cousin of man-with-a-hammer tendency.

This tendency is obviously problematic in our effort to simplify reality. When we see a powerful model work well, we tend to over-apply it, using it in non-analogous situations. We have trouble delimiting its usefulness, which causes errors.

Let's check out an example.

By most accounts, Ron Johnson was one the most successful and desirable retail executives by the summer of 2011. Not only was he handpicked by Steve Jobs to build the Apple Stores, a venture which had itself come under major scrutiny — one retort printed in Bloomberg magazine: "I give them two years before they're turning out the lights on a very painful and expensive mistake" — but he had been credited with playing a major role in turning Target from a K-Mart look-alike into the trendy-but-cheap *Tar-zhey* by the late 1990s and early 2000s.

Johnson's success at Apple was not immediate, but it was undeniable. By 2011, Apple stores were by far the most productive in the world on a per-square-foot basis and had become the envy of the retail world. Their sales figures left Tiffany's in the dust. The

gleaming glass cube on Fifth Avenue became a more popular tourist attraction than the Statue of Liberty. It was a lollapalooza, something beyond ordinary success. And Johnson had led the charge.

(History) offers a ridiculous spectacle of a fragment expounding the whole.

Will Durant

With that success, in 2011, Johnson was hired by Bill Ackman, Steven Roth, and other luminaries of the financial world to turn around the dowdy old department store chain JC Penney. The situation of the department store was dour: Between 1992 and 2011, the retail market share held by department stores had declined from 57% to 31%.

Their core position was a no-brainer, though. JC Penney had immensely valuable real estate, anchoring malls across the country. Johnson argued that their physical mall position was valuable if for no other reason than that people often parked next to them and walked through them to get to the center of the mall. Foot traffic was a given. Because of contracts signed in the '50s, '60s, and '70s, the heyday of the mall building era, rent was also cheap, another major competitive advantage. And unlike some struggling retailers, JC Penney made (some) money. There was cash in the register to help fund a transformation. The idea was to take the best ideas from his experience at Apple: great customer service, consistent pricing with no markdowns and markups, immaculate displays, and world-class products, and apply them to the department store.

Johnson planned to turn the stores into little malls-within-malls. He went as far as comparing the ever-rotating stores-within-a-store to Apple's "apps." Such a model would keep the store constantly fresh, and avoid the creeping staleness of retail.

Johnson pitched his idea to shareholders in a series of trendy New York City meetings reminiscent of Steve Jobs' annual "But wait, there's more!" product launches at Apple. He was persuasive: JC Penney's stock price went from \$26 in the summer of 2011 to \$42 in early 2012 on the strength of the pitch.

The idea failed almost immediately. His new pricing model (eliminating discounting) was a flop. The coupon hunters rebelled. Much of his new product was deemed too trendy. His new store model was wildly expensive for a middling department store chain – including operating losses purposefully endured, he'd spent several billion dollars trying to effect the physical transformation of the stores. JC Penney customers had no idea what was going on, and by 2013, Johnson was sacked. The stock price sank into the single digits, where it remains two years later.

What went wrong in the quest to build America's Favorite Store? It turned out that Johnson was using a map of Tulsa to navigate Tuscaloosa. Apple's products, customers, and history had far too little in common with JC Penney's. Apple had a rabid, young, affluent fan-base *before* they built stores; JC Penney's was not associated with youth or affluence. Apple had shiny products, and needed a shiny store; JC Penney was known for its affordable sweaters. Apple had never relied on discounting in the first place; JC Penney was taking *away* discounts given prior, triggering massive deprivation super-reaction.

All models are wrong but some are useful.

George Box

In other words, the old map was not very useful. Even his success at Target, which seems like a closer analogue, was misleading in the context of JC Penney. Target had made small, incremental changes over many years, to which Johnson had made a meaningful contribution. JC Penney was attempting to reinvent the concept of the department store in a year or two, leaving behind the core customer in an attempt to gain new ones. This was a much different proposition. (Another thing holding the company back was simply its base odds: Can you name a retailer of great significance that has lost its position in the world and come back?)

The main issue was *not* that Johnson was incompetent. He wasn't. He wouldn't have gotten the job if he was. He was *extremely* competent. But it was exactly his competence and past success that got him into trouble. He was like a great swimmer that tried to tackle a grand rapid, and the model he used successfully in the past, the map that had navigated a lot of difficult terrain, was not the map he needed anymore. He had an excellent theory about retailing that applied in some circumstances, but not in others. The terrain had changed, but the old idea stuck.

One person who well understands this problem of the map and the territory is Nassim Taleb, author of the *Incerto* series – *Antifragile*, *The Black Swan*, *Fooled by Randomness*, and *The Bed of Procrustes*.

Taleb has been vocal about the misuse of models for many years, but the earliest and most vivid I can recall is his firm criticism of a financial model called Value-at Risk, or VAR. The model, used in the banking community, is supposed to help manage risk by providing a maximum potential loss within a given confidence interval. In other words, it purports to allow risk managers to say that, within 95%, 99%, or 99.9% confidence, the firm will not lose more than \$X million dollars in a given day. The higher the interval, the less accurate the analysis becomes. It might be possible to say that the firm has \$100 million at risk at any time at a 99% confidence interval, but given the statistical properties of markets, a move to 99.9% confidence might mean the risk manager has to state the firm has \$1 billion at risk. 99.99% might mean \$10 billion. As rarer and rarer events are included in the distribution, the analysis gets less useful. So, by necessity, the “tails” are cut off somewhere and the analysis is deemed acceptable.

Elaborate statistical models are built to justify and use the VAR theory. On its face, it seems like a useful and powerful idea; if you know how much you can lose at any time, you can manage risk to the decimal. You can tell your board of directors and shareholders, with a straight face, that you've got your eye on the till.

The problem, in Nassim's words, is that:

A model might show you some risks, but not the risks of using it. Moreover, models are built on a finite set of parameters, while reality affords us infinite sources of risks.

In order to come up with the VAR figure, the risk manager must take historical data and assume a statistical distribution in order to predict the future. For example, if we could take 100 million human beings and analyze their height and weight, we could then predict the distribution of heights and weights on a *different* 100 million, and there would be a microscopically small probability that we'd be wrong. That's because we have a huge sample size and we are analyzing something with very small and predictable deviations from the average.

But finance does *not* follow this kind of distribution. There's no such predictability. As Nassim has argued, the “tails” are fat in this domain, and the rarest, most unpredictable events have the largest consequences. Let's say you deem a highly threatening event (for example, a 90% crash in the S&P 500) to have a 1 in 10,000 chance of occurring in a given year, and your historical data set only has 300 years of data. How can you accurately state the probability of that event? You would need far more data.

Thus, financial events deemed to be 5, or 6, or 7 standard deviations from the norm tend to happen with a certain regularity that nowhere near matches their supposed statistical probability. Financial markets have no biological reality to tie them down: We can say with a useful amount of confidence that an elephant will not wake up as a monkey, but we can't say anything with absolute confidence in an Extremistan arena.

We see several issues with VAR as a “map,” then. The first that the model is itself a severe abstraction of reality, relying on historical data to predict the future. (As all financial models must, to a certain extent.) VAR does *not* say “The risk of losing X dollars is Y, within a confidence of Z.” (Although risk managers treat it that way). What VAR actually says is “the

risk of losing X dollars is Y, *based on the given parameters*.” The problem is obvious even to the non-technician: The future is a strange and foreign place that we do not understand. Deviations of the past may not be the deviations of the future. Just because municipal bonds have never traded at such-and-such a spread to U.S. Treasury bonds does *not* mean that they won’t in the future. They just haven’t yet. Frequently, the models are blind to this fact.

In fact, one of Nassim’s most trenchant points is that on the day before whatever “worst case” event happened in the past, you would have *not* been using the coming “worst case” as your worst case, because it wouldn’t have happened yet.

Here’s an easy illustration. October 19, 1987, the stock market dropped by 22.61%, or 508 points on the Dow Jones Industrial Average. In percentage terms, it was then and remains the worst one-day market drop in U.S. history. It was dubbed “Black Monday.” (Financial writers sometimes lack creativity — there are several other “Black Monday’s” in history.) But here we see Nassim’s point: On October 18, 1987, what would the models use as the worst possible case? We don’t know exactly, but we do know the previous worst case was 12.82%, which happened on October 28, 1929. A 22.61% drop would have been considered so many standard deviations from the average as to be near impossible. But the tails are very fat in finance — improbable and consequential events seem to happen far more often than they should based on naive statistics. There is also a severe but often unrecognized *recursiveness* problem, which is that the models themselves influence the outcome they are trying to predict. (To understand this more fully, check out our post on Complex Adaptive Systems.)

A second problem with VAR is that even if we had a vastly more robust dataset, a statistical “confidence interval” does not do the job of financial risk management. Says Taleb:

There is an internal contradiction between measuring risk (i.e. standard deviation) and using a tool [VAR] with a higher standard error than that of the measure itself. I find that those professional risk managers whom I heard recommend a “guarded” use of the VAR on grounds that it “generally works” or “it works on average” do not share my definition of risk management. The risk management objective function is survival, not profits and losses. A trader according to the Chicago legend, “made 8 million in eight years and lost 80 million in eight minutes”. According to the same standards, he would be, “in general”, and “on average” a good risk manager.

This is like a GPS system that shows you where you are at all times but doesn’t include cliffs. You’d be perfectly happy with your GPS until you drove off a mountain.

It was this type of naive trust of models that got a lot of people in trouble in the recent mortgage crisis. Backward-looking, trend-fitting models, the most common maps of the financial territory, failed by describing a territory that was only a mirage: A world where home prices only went up. (Lewis Carroll would have approved.)

This was navigating Tulsa with a map of Tatooine.

The logical response to all this is, “So what?” If our maps fail us, how do we operate in an uncertain world? This is its own discussion for another time, and Taleb has gone to great pains to try and address the concern. Smart minds disagree on the solution. But one obvious key must be building systems that are robust to model error.

The practical problem with a model like VAR is that the banks use it to *optimize*. In other words, they take on as much exposure as the model deems OK. And when banks veer into managing to a highly detailed, highly confident model rather than to informed common sense, which happens frequently, they tend to build up hidden risks that will un-hide themselves in time.

If one were to instead assume that there *were* no precisely accurate maps of the financial territory, they would have to fall back on much simpler heuristics. (If you assume detailed statistical models of the future will fail you, you don't use them.)

In short, you would do what Warren Buffett has done with Berkshire Hathaway. Mr. Buffett, to our knowledge, has never used a computer model in his life, yet manages an institution half a trillion dollars in size by assets, a large portion of which are financial assets. How? The approach requires not only assuming a future worst case far more severe than the past, but also dictates building an institution with a robust set of backup systems, and margins-of-safety operating at multiple levels. Extra cash rather than extra leverage. Taking great pains to make sure the tails can't kill you. Instead of optimizing to a model, accept the limits of your clairvoyance.

When map and terrain differ, follow the terrain.

The trade-off, of course, is short-run rewards much less great than those available under more optimized models. Speaking of this, Charlie Munger has noted:

Berkshire's past record has been almost ridiculous. If Berkshire had used even half the leverage of, say, Rupert Murdoch, it would be five times its current size.

For Berkshire at least, the trade-off seems to have been worth it.

The salient point then is that in our march to simplify reality with useful models, of which Farnam Street is an advocate, we confuse the models with reality. For many people, the model creates its *own* reality. It is as if the spreadsheet comes to life. We forget that reality is a lot messier. The map isn't the territory. The theory isn't what it describes, it's simply a way we choose to interpret a certain set of information. Maps can also be *wrong*, but even if they are essentially correct, they are an abstraction, and abstraction means that information is lost to save space. (Recall the mile-to-mile scale map.)

How do we do better? This is fodder for another post, but the first step is to realize that *you do not understand a model, map, or reduction unless you understand and respect its limitations*. We must always be vigilant by stepping back to understand the context in which a map is useful, and where the cliffs might lie. Until we do that, we are the turkey.

70. How Analogies Reveal Connections, Spark Innovation, and Sell Our Greatest Ideas

Analogies are a means of drawing a parallel between two different things which we often use to convey complex ideas and to communicate effectively. We often use analogies to aid our reasoning. In this post, we explore how analogies work and how you can best utilize them.

John Pollack is a former Presidential Speechwriter. If anyone knows the power of words to move people to action, shape arguments, and persuade, it is he.

In Shortcut: How Analogies Reveal Connections, Spark Innovation, and Sell Our Greatest Ideas, he explores the powerful role of analogy in persuasion and creativity.

One of the key tools he uses for this is analogy.

While they often operate unnoticed, analogies aren't accidents, they're arguments—arguments that, like icebergs, conceal most of their mass and power beneath the surface. In arguments, whoever has the best argument wins.

But analogies do more than just persuade others — they also play a role in innovation and decision making.

From the bloody Chicago slaughterhouse that inspired Henry Ford's first moving assembly line, to the "domino theory" that led America into the Vietnam War, to the "bicycle for the mind" that Steve Jobs envisioned as a Macintosh computer, analogies have played a dynamic role in shaping the world around us.

Despite their importance, many people have only a vague sense of the definition.

What is an Analogy?

In broad terms, an analogy is simply a comparison that asserts a parallel—explicit or implicit—between two distinct things, based on the perception of a share property or relation. In everyday use, analogies actually appear in many forms. Some of these include metaphors, similes, political slogans, legal arguments, marketing taglines, mathematical formulas, biblical parables, logos, TV ads, euphemisms, proverbs, fables and sports clichés.

Because they are so disguised they play a bigger role than we consciously realize. Not only do analogies effectively make arguments, but they trigger emotions. And emotions make it hard to make rational decisions.

While we take analogies for granted, the ideas they convey are notably complex.

All day every day, in fact, we make or evaluate one analogy after the other, because some comparisons are the only practical way to sort a flood of incoming data, place it within the content of our experience, and make decisions accordingly.

Remember the powerful metaphor — that arguments are war. This shapes a wide variety of expressions like "your claims are indefensible," "attacking the weakpoints," and "You disagree, OK shoot."

Or consider the Map and the Territory — Analogies give people the map but explain nothing of the territory.

Warren Buffett is one of the best at using analogies to communicate effectively. One of my favorite analogies is when he noted "You never know who's swimming naked until the tide goes out." In other words, when times are good everyone looks amazing. When times suck, hidden weaknesses are exposed. The same could be said for analogies:

We never know what assumptions, deceptions, or brilliant insights they might be hiding until we look beneath the surface.

Most people underestimate the importance of a good analogy. As with many things in life, this lack of awareness comes at a cost. Ignorance is expensive.

Evidence suggests that people who tend to overlook or underestimate analogy's influence often find themselves struggling to make their arguments or achieve their goals. The

converse is also true. Those who construct the clearest, most resonant and apt analogies are usually the most successful in reaching the outcomes they seek.

The key to all of this is figuring out why analogies function so effectively and how they work. Once we know that, we should be able to craft better ones.

Don't Think of an Elephant

Effective, persuasive analogies frame situations and arguments, often so subtly that we don't even realize there is a frame, let alone one that might not work in our favor. Such conceptual frames, like picture frames, include some ideas, images, and emotions and exclude others. By setting a frame, a person or organization can, for better or worse, exert remarkable influence on the direction of their own thinking and that of others.

He who holds the pen frames the story. The first person to frame the story controls the narrative and it takes a massive amount of energy to change the direction of the story. Sometimes even the way that people come across information, shapes it — stories that would be a non-event if disclosed proactively became front page stories because someone found out.

In Don't Think of an Elephant, George Lakoff explores the issue of framing. The book famously begins with the instruction "Don't think of an elephant."

What's the first thing we all do? Think of an elephant, of course. It's almost impossible not to think of an elephant. When we stop consciously thinking about it, it floats away and we move on to other topics — like the new email that just arrived. But then again it will pop back into consciousness and bring some friends — associated ideas, other exotic animals, or even thoughts of the GOP.

"Every word, like elephant, evokes a frame, which can be an image of other kinds of knowledge," Lakoff writes. This is why we want to control the frame rather than be controlled by it.

In Shortcut Pollack tells of Lakoff talking about an analogy that President George W. Bush made in the 2004 State of the Union address, in which he argued the Iraq war was necessary despite the international criticism. Before we go on, take Bush's side here and think about how you would argue this point — how would you defend this?

In the speech, Bush proclaimed that "America will never seek a permission slip to defend the security of our people."

As Lakoff notes, Bush could have said, "We won't ask permission." But he didn't. Instead he intentionally used the analogy of permission slip and in so doing framed the issue in terms that would "trigger strong, more negative emotional associations that endured in people's memories of childhood rules and restrictions."

Commenting on this, Pollack writes:

Through structure mapping, we correlate the role of the United States to that of a young student who must appeal to their teacher for permission to do anything outside the classroom, even going down the hall to use the toilet.

But is seeking diplomatic consensus to avoid or end a war actually analogous to a child asking their teacher for permission to use the toilet? Not at all. Yet once this analogy has been stated (Farnam Street editorial: and tweeted), the debate has been framed. Those who would reject a unilateral, my-way-or-the-highway approach to foreign policy suddenly find themselves battling not just political opposition but people's deeply ingrained resentment of childhood's seemingly petty regulations and restrictions. On an even subtler level, the idea of not asking for a permission slip also frames the issue in terms of sidestepping bureaucratic paperwork, and who likes bureaucracy or paperwork.

Deconstructing Analogies

Deconstructing analogies, we find out how they function so effectively. Pollack argues they meet five essential criteria.

1. Use the highly familiar to explain something less familiar.

2. Highlight similarities and obscure differences.
3. Identify useful abstractions.
4. Tell a coherent story.
5. Resonate emotionally.

Let's explore how these work in greater detail. Let's use the example of master-thief, Bruce Reynolds, who described the Great Train Robbery as his Sistine Chapel.

The Great Train Robbery

In the dark early hours of August 8, 1963, an intrepid gang of robbers hot-wired a six-volt battery to a railroad signal not far from the town of Leighton Buzzard, some forty miles north of London. Shortly, the engineer of an approaching mail train, spotting the red light ahead, slowed his train to a halt and sent one of his crew down the track, on foot, to investigate. Within minutes, the gang overpowered the train's crew and, in less than twenty minutes, made off with the equivalent of more than \$60 million in cash.

Years later, Bruce Reynolds, the mastermind of what quickly became known as the Great Train Robbery, described the spectacular heist as "my Sistine Chapel."

Use the familiar to explain something less familiar

Reynolds exploits the public's basic familiarity with the famous chapel in the Vatican City, which after Leonardo da Vinci's Mona Lisa is perhaps the best-known work of Renaissance art in the world. Millions of people, even those who aren't art connoisseurs, would likely share the cultural opinion that the paintings in the chapel represent "great art" (as compared to a smaller subset of people who might feel the same way about Jackson Pollock's drip paintings, or Marcel Duchamp's upturned urinal).

Highlight similarities and obscure differences

Reynold's analogy highlights, through implication, similarities between the heist and the chapel—both took meticulous planning and masterful execution. After all, stopping a train and stealing the equivalent of \$60m—and doing it without guns—does require a certain artistry. At the same time, the analogy obscures important differences. By invoking the image of a holy sanctuary, Reynolds triggers a host of associations in the audience's mind—God, faith, morality, and forgiveness, among others—that camouflage the fact that he's describing an action few would consider morally commendable, even if the artistry involved in robbing that train was admirable.

Identify useful abstractions

The analogy offers a subtle but useful abstraction: Genius is genius and art is art, no matter what the medium. The logic? If we believe that genius and artistry can transcend genre, we must concede that Reynolds, whose artful, ingenious theft netted millions, is an artist.

Tell a coherent story

The analogy offers a coherent narrative. Calling the Great Train Robbery his Sistine Chapel offers the audience a simple story that, at least on the surface makes sense: Just as Michelangelo was called by God, the pope, and history to create his greatest work, so too was Bruce Reynolds called by destiny to pull off the greatest robbery in history. And if the Sistine Chapel endures as an expression of genius, so too must the Great Train Robbery. Yes, robbing the train was wrong. But the public perceived it as largely a victimless crime, committed by renegades who were nothing if not audacious. And who but the most audacious in history ever create great art? Ergo, according to this narrative, Reynolds is an audacious genius, master of his chosen endeavor, and an artist to be admired in public.

There is an important point here. The narrative need not be accurate. It is the feelings and ideas the analogy evokes that make it powerful. Within the structure of the analogy, the

argument rings true. The framing is enough to establish it succulently and subtly. That's what makes it so powerful.

Resonate emotionally

The analogy resonates emotionally. To many people, mere mention of the Sistine Chapel brings an image to mind, perhaps the finger of Adam reaching out toward the finger of God, or perhaps just that of a lesser chapel with which they are personally familiar. Generally speaking, chapels are considered beautiful, and beauty is an idea that tends to evoke positive emotions. Such positive emotions, in turn, reinforce the argument that Reynolds is making—that there's little difference between his work and that of a great artist.

Jumping to Conclusions

Daniel Kahneman explains the two thinking structures that govern the way we think: System one and system two. In his book, Thinking Fast and Slow, he writes "Jumping to conclusions is efficient if the conclusions are likely to be correct and the costs of an occasional mistake are acceptable, and if the jump saves much time and effort." "A good analogy serves as an intellectual springboard that helps us jump to conclusions," Pollack writes. He continues:

And once we're in midair, flying through assumptions that reinforce our preconceptions and preferences, we're well on our way to a phenomenon known as confirmation bias. When we encounter a statement and seek to understand it, we evaluate it by first assuming it is true and exploring the implications that result. We don't even consider dismissing the statement as untrue unless enough of its implications don't add up. And consider is the operative word. Studies suggest that most people seek out only information that confirms the beliefs they currently hold and often dismiss any contradictory evidence they encounter.

The ongoing battle between fact and fiction commonly takes place in our subconscious systems. In The Political Brain: The Role of Emotion in Deciding the Fate of the Nation, Drew Westen, an Emory University psychologist, writes: "Our brains have a remarkable capacity to find their way toward convenient truths—even if they are not all true."

This also helps explain why getting promoted has almost nothing to do with your performance.

Remember Apollo Robbins? He's a professional pickpocket. While he has unique skills, he succeeds largely through the choreography of people's attention. "Attention," he says "is like water. It flows. It's liquid. You create channels to divert it, and you hope that it flows the right way."

"Pickpocketing and analogies are in a sense the same," Pollack concludes, "as the misleading analogy picks a listener's mental pocket."

And this is true whether someone else diverts our attention through a resonant but misleading analogy—"Judges are like umpires"—or we simply choose the wrong analogy all by ourselves.

Reasoning by Analogy

We rarely stop to see how much of our reasoning is done by analogy. In a 2005 study published in the Harvard Business Review, Giovanni Gavettie and Jan Rivkin wrote: "Leaders tend to be so immersed in the specifics of strategy that they rarely stop to think how much of their reasoning is done by analogy." As a result they miss things. They make connections that don't exist. They don't check assumptions. They miss useful insights. By contrast "Managers who pay attention to their own analogical thinking will make better strategic decisions and fewer mistakes."

71. Shane Parrish on Mental Models, Decision Making, Charlie Munger, Farnam Street, And More

An interview I gave that I think you'll enjoy as I talk about reading, mental models, investing, learning and more.

Shane Parrish is the curator for the popular Farnam Street Blog, an intellectual hub of curated interestingness that covers topics like human misjudgment, decision making, strategy, and philosophy. Shane is a strategist for both individuals and organizations and is dedicated to mastering the best of what other people have already figured out.

Can you discuss your background and the origins of Farnam Street?

Farnam Street started as a byproduct of my MBA. As I was going through that program it became evident that we were being taught to regurgitate material in a way that made marking easier. We weren't honing our critical thinking skills or integrating multiple disciplines. We couldn't challenge anything.

Eventually, I got frustrated. I didn't give up on the MBA, but I did start using the time that I was previously investing in homework and started to focus on my own learning and development. At first it was mostly academic. I started going back to the original Kahneman and Tversky papers, and other material that was journal based, because I figured I'd probably never have access to such a wealth of journals again outside of school.

So I started the website and it was really just for me, not for anybody else. The original URL of the website was the zipcode for Berkshire Hathaway. I didn't think anyone would find it. It eventually grew into a community of people interested in continuous learning, applying different models to certain problems, and developing ways to improve our minds in a practical way. The strong reception surprised me at first, but now the community has become very large, stimulating, and encouraging. I should point out that I don't come up with anything original myself—I'm just trying to master the best of what other people like Buffett, Kaufman, Bevelin, and Munger have already figured out. In fact, that's our tagline. It reminds me of something Munger said once when asked what he learned from Einstein, and he replied, only half-jokingly, "Well he taught me relativity. I wasn't smart enough to figure that out on my own." That seems like a bit of a wiseass remark, but there's some untapped wisdom there.

What are your motivations for Farnam Street?

I want to embrace the opportunity I have, which has been created largely through luck, and I want to give readers and subscribers enormous value in three ways.

First, I want to help them make better decisions. To do our best to figure out how the world really works. Second, I want to help people discover new interests and connections across disciplines. Finally, I want to help people explore what it means to live a good life and how we should live. I hope by sharing my intellectual and personal journey I can help people better navigate theirs.

It seems pretty clear that you have a profound admiration for investors. Farnam Street is the street Berkshire Hathaway is located on, and you discuss Charlie Munger's views quite a bit. What appeals to you about investing?

For Munger and Buffett specifically, it's not necessarily that they're just investors, it is that they've modeled a path of life that resonates with me. I also appreciate the values that are associated with their investment success. I think what they've done is they've taken other people's ideas, stood on the shoulders of giants, so to speak, and applied those ideas in better ways than the people who came up with the ideas. For example, with regard to psychological biases and Kahneman's work, Munger and Buffett have found a way to institutionalize this to a point where they can actually avoid most of these biases.

Whereas Kahneman himself just says something along the lines of, “I’ve studied biases all my life, but I’m not better.” Yet, these two guys from Omaha actually figured out how to be better.

It’s not just Kahneman and human biases. They’ve done it in a variety of disciplines like Michael Porter’s work on Competitive Strategy. They separately derived the same basic ideas, except in a way that gives them an enormous investing advantage. To my knowledge, Michael Porter has not done that. Of course, he may not have been trying to do so. Another great example is Ben Graham. He provided the bedrock that Warren Buffett built his brain on, but if you really think about it, Buffett was and is a much better investor. And lastly, regarding Munger, in my opinion, his method of organizing practical psychology is a lot better than the actual residents of that discipline, even the people who “taught” him the ideas through books.

Returning to investing, the field resonates with me because investors have skin in the game. Investors have clear accountability and measurable performance. That contrasts with many other types organizations. For the most part, investors are searching for the truth and constantly looking for ways they could be wrong and that they could be fooling themselves. There’s a pretty clear scoreboard.

Are you an investor yourself?

Yes. I used to be involved with a small registered investment advisor based in Massachusetts. I still invest personally and hope to return more of my focus to investing in the future. (Which, I’ve now done at Syrus Partners) Right now I’m focused on Farnam Street, which I see as the biggest opportunity ahead of me and the opportunity that I’m most excited about. There’s a lot to do.

Can you talk about what you have planned for Farnam Street?

I just hired somebody to help out at Farnam Street for the first time. It’s become more of a sustainable business. We are developing products. We have two courses coming out next year that we’re incredibly excited about (Update: These two are now only available for members). I think we have put over a year’s effort into one of the products, and we’re just starting the other one right now which will be released next fall.

[quote]Adapting your reading style to consider the type of material you are reading and why you are reading it makes you much more effective at skimming, understanding, synthesizing, and connecting ideas. If you take the same approach to reading everything, you will end up overwhelmed and frustrated.[/quote]

We are launching “The Art of Reading” early in the year. That course is aimed at adapting Mortimer Adler’s theory of reading to the modern age, and giving people a structured way of going about learning from books, as opposed to simply reading them.

Seems simple, but most of us never really pick it up.

Today we are bombarded constantly with information, and we often read all types of material in the same way. But that’s pretty ineffective. We don’t have to read everything the same way.

Reading is something you seem to know quite a lot about, but in a recent post, you discussed that you are purposefully reading fewer books. What is your thinking around that decision?

I fell into a trap with reading. It almost became a personal challenge that you can easily get wrapped up in. In 2014, I was basically reading a book every few days. I think I ended the year with over 140 books read, but I must have started at least 300. I realized I was reading just to finish the book. That meant I wasn’t getting as much out of it as I should. I ended up wasting a lot of time using that approach and it also impacted what I read. You have these subtle pressures to read smaller books and to digest things in a really quick way. I wasn’t spending enough time synthesizing the material with what I already knew and honing my understanding of an idea.

[quote]It's not about how many books you read but what you get out of the books you read.[/quote]

It's not about how many books you read but what you get out of the books you read. One great book, read thoroughly and understood deeply, can have a more profound impact on your life than reading 300 books without really understanding the ideas in depth and having them available for practical problem-solving.

Can you discuss some of your techniques for absorbing and synthesizing as much information as possible?

There is a lot that can be done after simply finishing a chapter. I like to summarize the chapter in my own words. I also like to apply any learnings from the chapter to my life, either by looking backward to see where concepts may have applied or by looking forward to seeing if it might make sense to incorporate something into my daily routine. I think the reason to do that is twofold. One is to give me a better understanding of that learning, and two is really a check and balance, and a feedback loop. Have you ever watched TV and somebody comes in on a commercial and says, "What are you watching," and you're like, "I have no idea," but you've been sitting there 20 minutes? Well, we can do that with books too. You'll start reading, and paragraphs will fly by, and then you'll have no idea what you were reading. It's fine if you're reading for entertainment, you might be able to catch up later, but if you're reading for understanding, that's something you want to avoid. Part of what I want to do is develop a feedback process to make sure that I'm not doing that.

I try to make extensive use of book covers for notes about areas to revisit, potential connections to other concepts, and outlining the structure of the author's argument. After I've finished a book, I usually put it on my desk for a week or two, let it sit, and then I come back to it. I reread all of my margin notes, my underlines, and highlights. Then I apply a different level of filtering to it and make a decision about what I want to do with the information now.

You also talk about the Feynman technique in some of your posts.

The Feynman technique is essentially explaining a concept or idea to yourself, on a piece of paper, as if you were teaching it to someone else with little background knowledge. When you're learning something new, it's all about going back and making sure you understand it.

Can you explain it in simple, jargon-free, language? Can you explain it in a way that is complete and demonstrates understanding? Can you take an idea and apply it to a problem outside of the original domain? Take out a piece of paper and find out.

I think that being able to do this at the end of a book is really important, especially if it's a new subject for you. The process of doing that shows you where your gaps are; this is important feedback. If you have a gap in your understanding, you can circle back to the book to better understand that point. If you can't explain it to somebody else, then you probably don't understand it as well as you think you do. It doesn't mean you don't understand it, but the inability to articulate it is definitely a flag that it's something you need to circle back to, or pay more attention to.

"Most geniuses—especially those who lead others—prosper not by deconstructing intricate complexities but by exploiting unrecognized simplicities."

— Andy Benoit

It seems like feedback mechanisms are a key part of your approach.

I think at the heart of it, you want to be an active reader. You want to selectively be an active reader and not a passive reader. These types of activities make sure that you're reading actively. Writing notes in a book, for example, is really just a way to pound what you're reading into your brain. You need engagement.

In a recent post, you brought up Peter Thiel's concept of a "secret". Essentially, what important truth do very few people agree with you on? I'd be really curious if you have something in mind that would fit this concept.

Ever since I came across this question I've been toying with it over and over in my head. I'm not sure I have a decent answer, but I'll offer one of the things that I run into a lot but couldn't really describe until Peter Kaufman pointed me to a quote by Andy Benoit, who wrote a piece in Sports Illustrated a while back. Benoit said "Most geniuses—especially those who lead others—prosper not by deconstructing intricate complexities but by exploiting unrecognized simplicities." I think he nailed it. This explains Berkshire Hathaway, the New England Patriots, Costco, Glenair, and a host of amazing organizations.

I've long had a feeling about this but couldn't really pull it out of my subconscious into my conscious mind before. Benoit gave me the words. I think we generally believe that things need to be complicated but in essence, there is great value in getting the simple things right and then sticking with them, and that takes discipline. As military folks know, great discipline can beat great brainpower.

I know of many companies that invest millions of dollars into complicated leadership development programs, but they fail to treat their people right so the return on this investment isn't even positive it's negative because it fosters cynicism. Or consider companies that focus on complicated incentive plans—they never work. It's very simple. If you relentlessly focus on the basics and develop a good corporate culture—like the one Ken Iverson mentions in his book Plain Talk—you surpass people who focus on the complex. Where I might disagree with Benoit a little is that I don't think these are unrecognized as much as under-appreciated. People think the catechism has to be more complicated.

You discuss the power of multidisciplinary learning. Do you have any example where the multidisciplinary learning has been especially powerful for you? Munger has a number of examples of him arriving at a solution faster than an expert in a field as a virtue of Munger using concepts from other fields.

If you were a carpenter you wouldn't want to show up for a job with an empty toolbox or only a hammer. No, you'd want to have as many different tools at your disposal as possible.

[quote]Nothing sucks up your time like poor decisions.[/quote]

Furthermore, you'd want to know how to use them. You can't build a house with only a hammer. And there is no point in having a saw in your toolbox if you don't know how to use it. In this sense, we're all carpenters. Only, our tools are the big ideas from multiple academic disciplines. If we have a lot of mental tools and the knowledge of how to wield them properly, we can start to think rationally about the world.

These tools allow us to make better initial decisions, help us better scramble out of bad situations, and think critically about what other people are telling us. You can't overestimate the value of making good initial decisions. Nothing sucks up your time like poor decisions and yet, perversely, we often reward people for solving the very problems they should have avoided in the first place.

It's a little weird, but in some organizations, you're better off screwing up and fixing it than making a simple, correct, decision the first time. Think about portfolio managers trumpeting how they've "smartly sold" a stock at a loss of 20%, saving them a loss of 50%, but which a wiser person never would have purchased in the first place. The sale looks smart, but the easier decision would have been avoiding misery from the get-go. That kind of thing happens all over the place.

Multidisciplinary thinking also helps with cognitive diversity. In our annual workshop on decision making, Re:Think Decision Making, we talk about the importance of looking at a problem in multiple dimensions to better understand reality and identify the variables that will govern the situation—whether it's incentives, adaptation, or proximity effects. But the

only way you're going to get to this level of understanding is to hold up the problem and look at it through the lens of multiple disciplines. These models represent how the world really works. Why wouldn't you use them?

One important thing, for example, we can learn from ecology, is second-order thinking—"and then what?" I think that a lot of people forget that there's a next phase to your thinking, and there's a second and third order effect. I've been in a lot of meetings where decisions are made and very few people think to the second level. They get an idea that sounds good and they simply stop thinking. The brain shuts down. For example, we change classification systems or incentive systems in a way that addresses the available problems, but we rarely anticipate the new problems that will arise. It's not easy. This is hard work.

Another example is when a salesman comes into a company and offers you some software program he claims is going to lower your operating costs and increase your profits. He's got all these charts on how much more competitive you'll be and how it will improve everything. You think this is great. You're sold. Well, the second order thinking is to ask, how much of those cost savings are going to go to you and how much will be passed on to the customer? Well to a large extent that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitors' door and telling them you just bought their product. We know thanks to people like Garrett Hardin, Howard Marks, and disciplines like ecology that there are second and third order effects. This is how the world really works.

Munger's got a brain that I don't have. I have to deal with what I've got. I'm not trying to come up with the fastest solution to a problem. It's great to have a 30-second mind, but it's not a race. Part of the issue I see over and over again is not that people don't have the cognitive tools, but rather they don't have time to actually think about a problem in a three-dimensional way.

[quote]If you think you're going to come up with good solutions to complicated problems in 30 seconds and your name is not Charlie Munger, I wish you luck.[/quote]

The rest of us should learn to say "I don't know" or "Let me think about it" about ten times more frequently than we do.

It makes sense that second-order and third-order effects are underappreciated.

I think a lot of people get incentives wrong and it has disastrous implications on corporate culture. Let's look at it from another angle – how would you intentionally design an incentive system that functioned horribly? You'd make it so complicated that few people understood it. You'd make everyone measured on individual and not team success. You'd have different variables and clauses and sub-clauses. No one would understand how their work impacts someone else. To make it even worse, you'd offer infrequent and small rewards. You'd offer a yearly bonus of maybe 5% of salary or something. And of course, you'd allow the people in it to game the system and the people running it to turn it into politics. I think we can all agree those are not desired outcomes and yet that is how many incentive systems work.

[quote]I think it's important to focus on getting better at making decisions over time. It is about making the process slightly better than it was last time.[/quote]

Do you have any thoughts on particularly powerful concepts or process implementations that can help investment organizations pursue investment excellence?

I think it's important to focus on getting better at making decisions over time. It is about making the process slightly better than it was last time. These improvements compound like money. You really have to flip it on its head. What's likely to not work well? Generally speaking, analysts tend to have a focused view of the world and they stay in their lane. Specialization certainly helps develop specific knowledge, but it also makes it hard to learn from the guy or girl next to you who has knowledge in a different industry, so you're not improving your intuition as much as you'd probably want. It's like chess. People once

thought great chess players were great thinkers, but they're not any better at general problem-solving than the rest of us. They're just great chess players. Investment analysis is often the same way, especially if you're siloed in some industry analyst position. It's probably not making you a great thinker, but you are learning more about your industry. [quote] have the organization learn and get better, we need to expose our decision-making process to others.[/quote]

In order to have the organization learn and get better, we need to expose our decision making process to others. One way to do this is to highlight the variables we think are relevant. Start making clear why we made our decisions and the range of outcomes we thought were possible. It needs to be done in advance. A lot of people do this through a decision journal. Some accomplish this through a discussion that flushes out which variables you think will dominate the outcome and most importantly, why. Not only does that facilitate an environment where others can challenge your thought process, but over time it enables them to get a good feel for what you think are the key variables in that particular industry. That helps me expand my circle of competence. You don't want an organization where the automobile analyst knows nothing about banking and the chemicals guy knows little about consumer products, and then a portfolio manager with a little surface knowledge of everything is pulling the trigger. I have never seen that work, but I've seen a lot of people try. The "everyone's a generalist" approach has its own limitations, like a crippling lack of specialized knowledge.

So, obviously, any investment organization has to find a middle ground. How could it be otherwise? You must start with this basic and obvious truth to solve the problem. Another challenge in the investment world is dealing with the sheer volume of the information. I get questions from portfolio managers all the time about how best to keep up with the information flow. They say "I get 500 emails a day. I have researchers' work come to me at all hours. I have thousands of pages of material to read."

Clearly, Berkshire Hathaway has done a really good job with this, with basically two guys doing all of the information processing—two really smart guys, but only two.

How do they do that?

Well, part of the answer is that Buffett and Munger are continuously learning about companies that do not change rapidly. They're learning about companies that change slowly. That in and of itself is a major advantage. They also are operating in industries in which they know the key variables of determining an organization's success or failure, and more importantly, ignoring the industries where they don't. It's a huge step to be able say to yourself "Look, I'm going to miss some enormous winners that were incredibly hard to see ahead of time. I'm OK with that." Buffett and Munger can do it, but most struggle. So they stretch and invest in things where they really cannot accurately predict the odds of success or failure, all forces considered.

Probabilities being what they are, if you consistently invest in things with middling odds, you'll have middling results. Again, how could it be otherwise? The key is knowing the difference between an obviously attractive situation and a difficult-to-predict one and being able to act on the former and sit on the latter. Of course, I'm over-simplifying a bit, but you can't get around the fact that reality is reality. You have to find a way. And this will help you solve your information flow problem, because you'll be tossing a lot of ideas out very quickly.

It seems like you would prefer the Buffett and Munger model over the approach of the average hedge fund with specialists?

If my job is being a neurosurgeon, I need to keep up-to-date with all the latest neurosurgery papers, academic articles, books, and talks because I'm very specialized in that one particular area and it's relevant to my job and relevant to my livelihood.

If you look at investing holistically you can't do that for every company in every industry. In my understanding, part of the reason Buffett and Munger have accumulated so much

knowledge is that they focus on learning things that change slowly. That makes it easier to identify potential outcomes and determine the relevant variables. David Foster Wallace had this great quote, “Bees have to move very fast to stay still.” And that’s what most of us do. We move a lot to stay in the same place. Buffett and Munger are getting further ahead each day.

Unless physics changes, for example, it’s unlikely that we’ll see the development of more efficient ways to move bulk freight. It doesn’t seem subject to technological disruption, but instead will likely be aided by technology. Technology helps improve the management of your rail network, but it’s not going to replace the entire network anytime soon. I think that Berkshire is actually moving away from uncertainty by pursuing companies like this. If you don’t know the range of outcomes, you will have a hard time assessing probabilities. One of the things that decision journals help identify is outcomes outside of what we expected. That’s a very humbling experience. After identifying possible outcomes and applying confidence levels, it’s humbling to get it so wrong

You have also studied an investment firm that’s probably as different from Berkshire Hathaway as possible with your most recent podcast with Chris Dixon of Andreessen Horowitz. What are your thoughts on good decision making as applied in the venture capital world and how is it different than Berkshire Hathaway?

Chris was an excellent guest to have on The Knowledge Project. He operates in Venture Capital—a world I don’t get much exposure to. He has insight on things I know very little about: venture funding, how to structure a venture capital firm so that you are adding value, etc. And they’ve been very successful.

I think we’re largely operating in unprecedented territory given the magnitude of private valuations. In past decades, companies IPO’d at much lower valuations so public market investors could more easily participate in their success. I don’t know how this plays out, but talking to Chris was fascinating.

Andreessen Horowitz has a very different operational approach as compared to Berkshire Hathaway. As I understood it, they are trying to add value to the entrepreneurs. Also, they’ve moved away from a business or idea based sourcing process to one that is almost exclusively focused on the entrepreneur. That directly contradicts some of Buffett’s thoughts on the relative importance of a management team versus the underlying business.

It makes sense that they would have different approaches. I think it’s important to understand that there are things that we want to have in our mental tool box. But part of being an effective craftsman is knowing when they work and when they don’t. You can’t just pull out random tools and expect them to work.

In 2013, I did some consulting work on improving innovation in organizations and the most common thing that people were doing at the time to solve the innovation problem was copying Google’s 20% of time spent on independent innovative ideas.

[quote]You need to understand how that fits with the company culture.[/quote]

I found this interesting for a number of reasons. It surprised me that every executive had it on the tip of their tongue, but there’s no large sample size for a successful innovation like this 20% idea. Google and, I think, 3M are the two most prominent examples. Google, at the time, I think they had only been around for 15 years. That’s a pretty small sample size for continuous innovation. Also, you need to understand how that fits with the company culture, and why it works even if you’re seeing it work. Why does it work at Google? Is it because of how it fits in the overall culture? The problem I see is that people are taking one piece of a large puzzle and thinking that it’s going to solve their problem. It might help. It might not. It’s just a tool. It reminds me of the group of blind people touching the different parts of the elephant.

Also, some of these innovation projects get done for the wrong reasons, and with the wrong incentives. If my boss asks me for ideas to help the company innovate and I give

him an idea that sounds good, one that subconsciously reminds him of an article he read in Fortune about innovation, isn't that basically good enough for me as an employee? Does it even matter if it works? In most organizations, am I really going to be held responsible for the success or failure of my innovation prescription? The organization might suffer, but will I suffer personally? Probably not. My lack of ability to think the problem through will probably be forgotten in time if the idea sounded good and relevant at the time. If it was defensible via Powerpoint. This is one reason hiring consultants rarely works as well as hoped.

So, we copy Google's twenty percent innovation time. They're an innovative company; they're hip; they're cool; we're going to copy them. Okay, well, we can do that. It's a good story. What gets lost is a potentially useful discussion like, "Maybe we should remove the things in our environment that take away from natural innovation, like all these meetings." That's a much tougher conversation, but just like taking away sugar works better than adding broccoli to your diet, taking things out of the corporate culture is often a better solution than adding new stuff. Munger has us paying attention to incentives because they really are driving the train. You have to get it right.

One big theme for you is the concept of life-long learning. What is your motivation to pursue it? Munger has called it a moral duty. Do you have similar feelings?

I wish I were as eloquent as him. I've always had to work harder. You just have to keep getting better every day. You have to keep learning. If you're going to accomplish what you want to accomplish, it's probably not through going home and watching Netflix every night, right? You have to learn how the world works. We have a huge statistical sample size of things that aren't changing. There is an excellent letter by Chris Begg at East Coast Asset Management that discusses Peter Kaufman's thoughts on this. Physics, math, and biology are things that change very, very slowly, if at all. Learning things in those disciplines is good. It's practical, because that's how the world works. Those are things that don't change over time.

I think that, for me, it's just become "How can I pass people that are smarter than me?" I think if I can get incrementally better every day, compounding will kick in and over a long enough time, I'm going to achieve the things that I want in life.

What could be better than constantly learning new things and discovering that you're still curious? Most of us forget what it's like to be six years old and asking "why?" all the time and trying to understand why things operate the way they do. It's hard to still do that, but you can still carry that wonder with you into life and try to understand why things are happening and why success or failure happens.

[quote]Avoiding stupidity is easier than seeking brilliance. But that by itself is suboptimal. You also want to copy models of success. [/quote]

We don't necessarily have to come up with all of this stuff ourselves. We can see a better model and adopt it or, the parts of it that will help us along. Giving up on holding on to our own ideas is really important.

I don't come up with almost anything that's original. I aggregate and synthesize other people's thoughts and put it into context for people. I think that those are things that I like to focus on, I have a passion for doing that. I'm doing it anyway because I get a lot of value out of reading, learning, and exploring the world, and I share that with people.

With regard to Mental Models, you spend a lot of time discussing their importance, but you also highlight their shortcomings. Can you discuss your view of the value of mental models?

It's important to understand how we are likely to fool ourselves. Aside from the psychological factors, which Munger and Bevelin talk about extensively, there are other ways.

For example, we run organizations based on dashboards and metrics and we make decisions based on these numbers. Investors look at financial reports to make investment decisions.

We think that those numbers tell a story and, to some extent, they do. However, they don't tell the full story. They are limited. For example, a strike-out can be a good thing in baseball. Players who suck statistically in one system can thrive as a part of another – the whole “Moneyball” idea lives here, and the Patriots have been extremely successful with a wide variety of talent. In business, reported depreciation can be widely off. The accounting could be gamed. A tailwind could be benefitting a business temporarily, soon to dissipate. Many companies look their absolute best, on historical figures, just before the big denouement.

“All models are false but some are useful.”

— George Box

There is a great quote by George Box who said “All models are false but some are useful.” Practically speaking, we have to work with reductions—like maps. A map with a scale of one foot to one foot wouldn't be useful, would it? Knowing that we're working with reductions of reality, not reality itself, should give us pause. We recently wrote a piece on Farnam Street called “The Map is Not the Territory,” which is a more in-depth exploration of the nuances behind this.

Knowing how to dig in and understand these maps and their limitations is important. A lot of models are core – they don't change very much. Social proof is real. Incentives do drive human behavior, financial and otherwise. The margin of safety approach from engineering works across many, many practical areas of life. Those are the types of huge, important models you want to focus on as a part of becoming a generally wise person. You need to learn them and learn how to synthesize with them. From there, you layer in the models that are specific to your job or your area of desired expertise. If you're a bank investor, you're going to look to attain a deep fluency in bank accounting that a neurosurgeon wouldn't need. But both the analyst and the surgeon can understand and use the margin of safety idea practically and profitably.

Essentially, they can be powerful if used correctly, but we can also over apply them in some ways?

They work sometimes and not other times. You need to be aware of limitations. The point here is just to be cautious—the map is not the terrain. It doesn't tell the full story.

Do you have any other investors or companies outside of Berkshire Hathaway that really have some profound thinking or you really love reading their shareholder letters or you've learned a lot from? Anything like that that we can talk about?

Berkshire has an incredibly unique model of writing to shareholders, and frankly no one else is as good. One that's slightly off the beaten path, although it's become a lot better known over the past few years, is a Canadian company called Constellation Software (CSU). The CEO there is truly doing God's work as far as how he reports to shareholders. Very clear presentation of the financial performance of the business, and a lucid and honest discussion of what's going on.

There are two key components to reporting to shareholders well, as I see it. One is presenting, in as clear a way as possible, the results in the prior periods. Presented consistently and honestly over time. The second is being extremely forthcoming about why these figures came out the way they did; good or bad, warts and all. When Blue Chip Stamps was still a reporting company, Munger would write about See's Candy. What did his summary table show every year? Pounds of candy sold, stores open, total revenue, total profits. The key variables. Then he explained in clear language why See's was a good business and what had occurred in the most recent period, and if possible, what he

foresaw in general for the following year. That's what we need more of: give investors an updated report of the major drivers and then tell us what happened. Leave out the fluff. You don't need to write essays like Buffett. Just help us understand the business and what's going on.

This has been great, Shane. Thanks so much for your time.

72. How Clever Leaders Overcome More Talented and Better Funded Competitors

Talent and resources aren't always enough to succeed. Doing incredible things requires true passion. Sometimes a driven, inspired team can succeed against one with more talent and funding.

In the early 1900s Samuel Pierpont Langley wanted to be the first man to fly an airplane. He stacked the odds in his favor, or so he thought, by arming himself with all the ingredients for success.

His friends included some of the most powerful men in government and business. He was given a \$50k grant from the War Department (an enormous sum at the time.) He brought together the best minds of the day – the most talented team imaginable. The team had access to the best technology and materials. They were treated like rockstars and followed everywhere by the press.

It was virtually impossible to fail. Or was it?

Not very far away Wilbur and Orville Wright were working on their own airplane. Only they didn't have a lot of money. They didn't have a team of world-class talent – not a single person on the team had a college education let alone an advanced degree. They didn't have the best materials. Heck, they were operating out of a bicycle shop. But they did have something that Pierpont didn't have. They had passion.

That passion was so intense, writes Simon Sinek in his book It Starts With Why, “that it inspired the enthusiasm and commitment of a dedicated group in their hometown of Dayton, Ohio.”

Like the Titanic, we know how this story ends.

On December 17, 1903 the Wright brothers took man into flight for the first time.

Why did they succeed against a more talented and better funded team?

It wasn't luck. Both Langley and the Wright brothers were motivated, had scientific minds, and worked hard. It wasn't money, talent, or materials. Langley had more of these in spades. It wasn't systems or processes as these are easily replicated.

The difference was that the Wright brothers, according to Sinek, “were able to inspire those around them and truly lead their team to develop a technology that would change the world.”

Passion can trump talent

The difference between someone doing something because they want to and not because they have to is huge.

Have you ever worked for a boss you didn't like on a project you didn't like? You might be the most talented person in the organization but it doesn't matter because on that project and for that boss you're a 9 to 5 worker. You do your job and nothing more. You shut your brain off.

Compare that to a time you worked for a boss you loved on a project you loved. I bet you went all in. The hours flew by, you thought about the project in the shower in the morning, your passion and excitement about the project was hard to contain.

The difference between these two examples is not a few hours of a day. The difference is non-linear. (And anytime you get a non-linear result when you expected a linear one, you need to pay attention as the world is trying to teach you something.)

This is how team can trump talent and one of the main reasons that culture eats strategy. Sinek concludes that great leaders "are able to inspire people to act. Those who are able to inspire give people a sense of purpose or belonging that has little to do with any external incentive or benefit to be gained." In short, they inspire people to act because they want to, not because they were swayed with money or rewards. And people who are inspired to act have a deeply personal motivation for doing so and they endure inconveniences, personal suffering and setbacks.

Give me a team of people acting because they want to, not because they have to, and you can compete with anyone.

73. Second-Order Thinking: What Smart People Use to Outperform

Understanding how to think things through – to push your mind past the first step – can help you solve problems, avoid problems, and take better actions.

The best way to examine the long-term consequences of our decisions is to think things through. This is called use second-order thinking.

It's often easier to identify when people don't adequately consider the second and subsequent-order impacts. For example, consider a country that, wanting to inspire regime change in another country, funds and provides weapons to a group of "moderate rebels." Only it turns out that those moderate rebels will become powerful and then go to war with the sponsoring country for decades. Whoops.

Failing to consider second- and third-order consequences is the cause of a lot of painfully bad decisions, and it is especially deadly when the first inferior option confirms your own biases. Never seize on the first available option, no matter how good it seems, before you've asked questions and explored.

The ability to think through problems to the second, third, and nth order—or what we will call second-order thinking for short—is a powerful thinking tool that not only solves problems but avoids them.

Second-Order Thinking

In his book, *The Most Important Thing*, Howard Marks explains the concept of second-order thinking, which he calls second-level thinking.

First-level thinking is simplistic and superficial, and just about everyone can do it (a bad sign for anything involving an attempt at superiority). All the first-level thinker needs is an opinion about the future, as in "The outlook for the company is favorable, meaning the stock will go up." Second-level thinking is deep, complex and convoluted.

First-order thinking is fast and easy. It happens when we look for something that only solves the immediate problem without considering the consequences. For example, you can think of this as I'm hungry, so let's eat a chocolate bar.

Second-order thinking is more deliberate. It is thinking in terms of interactions and time, understanding that despite our intentions our interventions often cause harm. Second order thinkers ask themselves the question "And then what?" This means thinking about the consequences of repeatedly eating a chocolate bar when you are hungry and using that to inform your decision. If you do this you're more likely to eat something healthy.

First-level thinking looks similar. Everyone reaches the same conclusions. This is where things get interesting. The road to out-thinking people can't come from first-order thinking. It must come from second-order thinking. Extraordinary performance comes from seeing things that other people can't see.

Improving Your Ability To Think

Here are some ways to put second-order thinking into practice today.

1. Always ask yourself, "And then what?"
2. Think across time — What do the consequences look like in 10 minutes? 10 months? 10 Years?
3. Create templates like the second image above with 1st, 2nd, and 3rd order consequences. Identify your decision, think it through, and write down the consequences. If you review these regularly you'll be able to help calibrate your thinking.
4. If you're using this to think about business decisions, ask yourself how important parts of the ecosystem are likely to respond. How will employees deal with this? What will my competitors likely do? What about my suppliers? What about the regulators? Often, the answer will be little to no impact, but you want to understand the immediate and second-order consequences before you make the decision.

A lot of extraordinary things in life are the result of things that are first-order negative, second order positive. So just because things look like they have no immediate payoff, doesn't mean that's the case. All it means is that you'll have less competition if the second and third order consequences are positive because everyone who thinks at the first order won't think things through.

Second-order thinking takes a lot of work. It's not easy to think in terms of systems, interactions, and time. However, doing so is a smart way to separate yourself from the masses.

74. Avoiding Falling Victim to The Narrative Fallacy

The narrative fallacy leads us to see events as stories, with logical chains of cause and effect. Stories help us make sense of the world. However, if we're not aware of the narrative fallacy it can lead us to believe we understand the world more than we really do.

A typical biography starts by describing the subject's young life, trying to show how the ultimate painting began as just a sketch. In Walter Isaacson's biography of Steve Jobs, for example, Isaacson illustrates that Jobs's success was determined to a great degree by the childhood influence of his father. Paul Jobs, a careful, detailed-oriented engineer and craftsman – would carefully craft the backs of fences and cabinets even if no one would see – who Jobs later found out was not his biological father. The combination of his adoption and his craftsman father planted the seeds of Steve's adult personality: his penchant for design detail, his need to prove himself, his messianic zeal. The recent movie starring Michael Fassbender especially plays up the latter cause; Jobs's feeling of abandonment drove his success. Fassbender's emotional portrayal earned him an Oscar nomination.

Nassim Taleb describes a memorable experience of a similar type in his book *The Black Swan*.

In Rome, Taleb is having an animated discussion with a professor who has read his first book *Fooled by Randomness*, parts of which promote the idea that our mind creates more cause-and-effect links than reality would support. The professor proceeds to congratulate Taleb on his great luck by being born in Lebanon:

... had you grown up in a Protestant society where people are told that efforts are linked to rewards and individual responsibility is emphasized, you would never have seen the world in such a manner. You were able to see luck and separate cause-and-effect because of your Eastern Orthodox Mediterranean heritage.

These types of stories strike a deep chord: They give us deep, affecting reasons on which to hang our understanding of reality. They help us make sense of our own lives. And, most importantly, they frequently cause us to believe we can predict the future. The problem is, most of them are a sham.

As flattered as he was by the professor's praise, Nassim Taleb knew instantly that attributing his success to his background was a fallacy:

How do I know that this attribution to the background is bogus? I did my own empirical test by checking how many traders with my background who experienced the same war become skeptical empiricists, and found none out of twenty-six.

The professor who had just praised the idea that we overestimate our ability to understand cause-and-effect couldn't stop himself from committing the very same error in conversation with Taleb himself.

Steve Jobs felt the same about the idea that his adoption had anything but a coincidental effect on his success:

There's some notion that because I was abandoned, I worked very hard so I could do well and make my parents wish they had me back, or some such nonsense, but that's ridiculous [...] Knowing I was adopted may have made me feel more independent, but I have never felt abandoned. I've always felt special. My parents made me feel special.

The Narrative Fallacy

Such is the power of the Narrative Fallacy — the backward-looking mental tripwire that causes us to attribute a linear and discernable cause-and-effect chain to our knowledge of the past. As Nassim points out, there is a deep biological basis to the problem: we are inundated with so much sensory information that our brains have no other choice; we must put things in order so we can process the world around us. It's implicit in how we understand the world. When the coffee cup falls, we need to know why it fell. (We knocked

it over.) If someone gets the job instead of us, we need to know why they were deemed better. (They had more experience, they were more likeable.) Without a deep search for reasons, we would go around with blinders on, one thing simply happening after another. The world does not make sense without cause-and-effect.

This necessary mental function serves us well, in general. But we also must come to terms with the types of situations where our broadly useful “ordering” function causes us to make errors.

What You Don't See

We fall for narrative regularly and in a wide variety of contexts. Sports are the most obvious example: Try to recall the last time you watched a profile of a famous athlete — the rise from obscurity, the rags-to-riches story, the dream-turned-reality. How did ESPN portray the success of the athlete?

If it was like most profiles, you'd most likely see some combination of the following:

Parents or a coach that pushed him/her to strive for excellence; a natural gift for the sport, or at the very least, a strong inborn athleticism; an impactful life event and/or some form of adversity; and a hard work ethic.

The copy might read as follows,

It was clear from a young age that Steven was destined for greatness. He was taller than his whole class, had skills that none of his peers had, and a mother who never let him indulge laziness or sloth. Losing his father at a young age pushed him to work harder than ever, knowing he'd have to support his family. And once he met someone willing to tutor him, someone like Central High basketball coach Ed Johnson, the future was all but assured — Steven was going to be an NBA player come hell or high-water.

If you were to read this story about how a tall, strong, fast, skilled young man with good coaching and a hard work ethic came to dominate the NBA, would you stop for even a second to question that those were the total causes of his success? If you're like most people, the answer is no. We hear about similar stories over and over again.

The problem is, these stories are subject to a deep narrative fallacy. Here's why: think again about the supposed causes of Steven's success — work ethic, great parents, strong coaching, a formative life event. How many young men in the United States alone have the exact same background and yet failed to achieve their dreams of NBA stardom? The question answers itself: there are probably thousands of them.

That's the problem with narrative: it lures us into believing that we can explain the past through cause-and-effect when we hear a story that supports our prior beliefs. To take the case of our fictitious basketball player, we have been conditioned to believe that hard work, pushy parents, and coaches, and natural gifts lead to fame and success.

To be clear, many of these factors are contributive in important ways. There aren't many short, slow guys with no work ethic and bad hand-eye coordination playing in the NBA. And passion goes a long way towards deserved success. But if it's true that there are a thousand times as many similarly qualified men who do not end up playing professional basketball, then our diagnosis must be massively incomplete. There is no other sensible explanation.

What might we be missing? The list is endless, but some combination of luck, opportunism, and timing must have played into Steven's and any other NBA player's success. It is very difficult to understand cause-and-effect chains, and this is a simple example compared to a complex case like a war or an economic crisis, which would have had multiple causes working in a variety of directions and enough red herrings to make a proper analysis difficult.

When it comes to understanding success in basketball, the problem might seem benign. (Although if you're an NBA executive, maybe not so benign.) But the rest of us deal with it in a practical way all the time. Taleb points out in his book that you could prove how narratives influence our decision making by giving a friend a great detective novel and

then, before they got to the final reveal, asking them to give the odds of each individual suspect being the culprit. It's almost certain that unless you allowed them to write down the odds as they went along, they'd add up to more than 100% — the better the novel, the higher the number. This would be nonsense from a probability standpoint, the odds must add to 100%, but each narrative is so strong that we lose our bearings.

Of course, the more salient the given reasons, the more likely we are to attribute them as causes. By salient, we mean evidence which is mentally vivid and seemingly relevant to the situation — as in the case of the young basketball prodigy losing his father, a common, Disney-made plot point. We cling to these highly available images and they cause us to make avoidable errors in judgment, as with those of us afraid to board an airplane because of the thought of a harrowing airplane crash, one that is statistically unlikely to occur in many thousands of lifetimes.

Less is More

Daniel Kahneman makes this point wonderfully in his book *Thinking: Fast, and Slow*, in a chapter titled “Linda: Less is More”.

The best-known and most controversial of our experiments involved a fictitious lady called Linda. Amos and I made up the Linda problem to provide conclusive evidence of the role of heuristics in judgment and of their incompatibility with logic. This is how we described Linda:

Linda is thirty-one years old, single, outspoken, and very bright. She majored in philosophy. As a student, she was deeply concerned with issues of discrimination and social justice, and also participated in antinuclear demonstrations.

[...]

In what we later described as an “increasingly desperate” attempt to eliminate the error, we introduced large groups of people to Linda and asked them this simple question:

Which alternative is more probable?

Linda is a bank teller.

Linda is a bank teller and is active in the feminist movement.

This stark version of the problem made Linda famous in some circles, and it earned us years of controversy. About 85% to 90% of undergraduates at several major universities chose the second option, contrary to logic.

This again demonstrates the power of narrative. We are so willing to take a description and mentally categorize the person it describes — in this case, feminist bank teller is much more salient than simply bank teller — that we will violate probabilities and logic in order to uphold our first conclusion. The extra description makes our mental picture much more vivid, and we conclude that the vivid picture must be the correct one. This error very likely contributes to our tendency to stereotype based on limited sample sizes; a remnant of our primate days which probably served us well in a very different environment.

The point is made again by Kahneman as he explains how the corporate performance of companies included in famous business books like *In Search of Excellence* and *Good to Great* regressed to the mean after the books were written, a now well-known phenomenon:

You are probably tempted to think of causal explanations for these observations: perhaps the successful firms became complacent, the less successful firms tried harder. But this is the wrong way to think about what happened. The average gap must shrink, because the original gap was due in good part to luck, which contributed both to the success of the top firms and to the lagging performance of the rest. We have already encountered this statistical fact of life: regression to the mean.

Stories of how businesses rise and fall strike a chord with readers by offering what the human mind needs: a simple message of triumph and failure that identifies clear causes and ignores the determinative power of luck and the inevitability of regression. These

stories induce and maintain an illusion of understanding, imparting lessons of enduring value to readers who are all too eager to believe them.

What's the harm, you say? Aren't we just making our lives a little more interesting with these stories? Very true. Stories serve many wonderful functions: teaching, motivating, inspiring. The problem though is that we too often believe our stories are predictive. We make them more real than they are. The writers of the business case-study books certainly believed that the explanations of success they put forth would be predictive of future success (the title *Built to Last* certainly implies as much), yet a good many of the companies soon became shells of their former selves – Citigroup, Hewlett Packard, Motorola, and Sony among them.

Is a good corporate culture helpful in generating success? Certainly! As it is with height and NBA success. But it's far more difficult to determine cause and effect than simply recognizing the no-brainers. Just as many tall, talented, hard-working basketball players have failed to make it, many corporate cultures which met all of the *Built to Last* structures have subsequently failed. The road to success was simply more complicated than the reductive narrative of the book would allow. Strategic choices, luck, circumstance, and the contributions of specific individual personalities may have all played a role. It's hard to say. And unless we recognize the Narrative Fallacy for what it is, a simplified and often incorrect view of past causality, we carry an arrogance about our knowledge of the past and its usefulness in predicting the future.

Reason-Respecting Tendency

A close cousin of the narrative fallacy is what Charlie Munger refers to as Reason-Respecting Tendency in *Poor Charlie's Almanack*. Here's how Charlie describes the tendency:

There is in man, particularly one in an advanced culture, a natural love of accurate cognition and a joy in its exercise. This accounts for the widespread popularity of crossword puzzles, other puzzles, and bridge and chess columns, as well as all games requiring mental skill.

This tendency has an obvious implication. It makes man especially prone to learn well when a would-be teacher gives correct reasons for what is being taught, instead of simply laying out the desired belief ex-cathedra with no reasons given. Few practices, therefore, are wiser than not only thinking through reasons before giving orders but also communicating these reasons to the recipient of the order.

[...]

Unfortunately, Reason-Respecting Tendency is so strong that even a person's giving of meaningless or incorrect reasons will increase compliance with his orders and requests. This has been demonstrated in psychology experiments wherein "compliance practitioners" successfully jump to the head of lines in front of copying machines by explaining their reason: "I have to make some copies." This sort of unfortunate byproduct of Reason-Respecting Tendency is a conditioned reflex, based on a widespread appreciation of the importance of reasons. And, naturally, the practice of laying out various claptrap reasons is much used by commercial and cult "compliance practitioners" to help them get what they don't deserve.

The deep structure of the mind is such that stories, reasons, and causes, things that point an arrow in the direction of *Why* are the ones that stick most deeply. Our need to look for cause-and-effect chains in anything we encounter is simply an extension of our inbuilt pattern recognition software, which can deepen and broaden as we learn new things. It has been shown, for example, that a master chess player cannot remember the pieces on a randomly assembled chessboard any better than a complete novice. But a master chess player can memorize the pieces on a board which represents an actual game in progress. If you take the pieces away, the master can replicate their positions with very high fidelity, whereas a novice cannot. The difference is that the pattern recognition software of the

chess player has been developed to a high degree through deliberate practice — they have been in a thousand game situations just like it in the past. And while most of us may not be able to memorize chess games, we all have brains that perform the same function in other contexts.

Taleb hits on the same idea in *The Black Swan*:

Consider a collection of words glued together to constitute a 500-page book. If the words are purely random, picked up from the dictionary in a totally unpredictable way, you will not be able to summarize, transfer, or reduce the dimensions of that book without losing something significant from it. You need 100,000 words to carry the exact message of a random 100,000 words with you on your next trip to Siberia. Now consider the opposite: a book filled with the repetition of the following sentence: “The chairman of [insert here your company’s name] is a lucky fellow who happened to be in the right place at the right time and claims credit for the company’s success, without making a single allowance for luck,” running ten times per page for 500 pages. The entire book can be accurately compressed, as I have just done, into 34 words (out of 100,000); you could reproduce it with total fidelity out of such a kernel.

If we combine the ideas of Reason-Respecting Tendency and the mind’s deep craving for order, the interesting truth is that the best teaching, learning, and storytelling methods — those involving reasons and narrative, on which our brain can store information in a more useful and efficient way — are also the ones that cause us to make some of the worst mistakes. Our craving for order betrays us.

What Can We Do?

The first step, clearly, is to become aware of the problem. Once we understand our brain’s craving for narrative, we begin to see narratives every day, all the time, especially as we consume news. The key question we must ask ourselves is “Of the population of X subject to the same initial conditions, how many turned out similarly to Y? What hard-to-measure causes might have played a role?” This is what we did when we unraveled Steven’s narrative above. How many kids just like him, with the same stated conditions — tall, skilled, good parents, good coaches, etc. — achieved the same result? We don’t have to run an empirical test to understand that our narrative sense is providing some misleading cause-and-effect. Common sense tells us there are likely to be many more failures than successes in that pool, leading us to understand that there must have been other unrealized factors at play; luck being a crucial one. Some identified factors were necessary but not sufficient — height, talent, and coaching among them — and some factors might have been negligible or even negative. (Would it have helped or hurt Steven’s NBA chances if he had not lost his father? Impossible to say.)

Modern scientific thought is built on just this sort of edifice to solve the cause-and-effect problem. A thousand years ago, much of what we thought we knew was based on naïve backward-looking causality. (Steve put leeches on his skin and then survived the plague = leeches cure the plague.) Only when we learned to take the concept of [leeches = cure for plague] and call it a hypothesis did we begin to understand the physical world. Only by downgrading our naïve assumptions to the status of a hypothesis, which needs to be tested with rigorous experiment – give 100 plague victims leeches and let 100 of them go leech-less and tally the results – did we find a method to parse actual cause and effect. And it is just as relevant to ask ourselves the inverse of the question posed above: “Of the population not subject to X, how many still ended up with the results of Y?” This is where we ask: which basketball players had intact families, easy childhoods, and, yet ended up in the NBA anyway? Which corporations lacked the traits described in Good to Great but achieved Greatness anyway? When we are willing to ask both types of questions and try our best to answer them, we can start to see which elements are simply part of the story rather than causal contributors.

A second way we can circumvent narrative is to simply avoid or reinterpret sources of information most subject to the bias. Turn the TV news off. Stop reading so many newspapers. Be skeptical of biographies, memoirs, and personal histories. Be careful of writers who are incredibly talented at painting a narrative, but claim to be writing facts. (I love Malcolm Gladwell's books, but he would be an excellent example here.) We learned above that narrative is so powerful it can overcome basic logic, so we must be rigorous to some extent about what kinds of information we allow to pass through our filters. Strong narrative flow is exactly why we enjoy a fictional story, but when we enter the non-fiction world of understanding and decision making, the power of narrative is not always on our side. We want to use narrative to our advantage — to teach ourselves or others useful concepts — but be wary of where it can mislead.

One way to assess how narrative affects your decision-making is to start keeping a journal of your decisions or predictions in any arena that you consider important. It's important to note the why behind your prediction or decision. If you're going to invest in your cousin's new social media startup — sure to succeed — explain to yourself exactly why you think it will work. Be detailed. Whether the venture succeeds or fails, you will now have a forward-looking document to refer to later, so that when you have the benefit of hindsight, you can evaluate your original assumptions instead of finding convenient reasons to justify the success or failure. The more you're able to do this exercise, the more you'll come to understand how complicated cause-and-effect factors are when we look ahead rather than behind.

Munger also gives us a few prescriptions in *Poor Charlie's Almanack* after describing the Availability Bias, another kissing cousin of the Narrative Fallacy and the Reason-Respecting Tendency. We are wise to take heed of them as we approach our fight with narrative:

The main antidote to miscues from the Availability-Misweighing Tendency often involves procedures, including use of checklists, which are almost always helpful.

Another antidote is to behave somewhat like Darwin did when he emphasized disconfirming evidence. What should be done is to especially emphasize factors that don't produce reams of easily available numbers, instead of drifting mostly or entirely into considering factors that do produce such numbers. Still another antidote is to find and hire some skeptical, articulate people with far-reaching minds to act as advocates for notions that are opposite to the incumbent notions. [Ed: Or simply ask a smart friend to do the same.]

One consequence of this tendency is that extra-vivid evidence, being so memorable and thus more available in cognition, should often consciously be under weighed while less vivid evidence should be overweighed.

Munger's prescriptions are almost certainly as applicable to solving the narrative problem as the close-related Availability problem, especially the issue we discussed earlier of vivid evidence.

Lastly, the final prescription comes from Taleb himself; the progenitor of the idea of our problem with narrative: when searching for real truth, favor experimentation over storytelling (data over anecdote), favor experience over history (which can be cherry-picked), and favor clinical knowledge over grand theories. Figure out what you know and what's a guess, and become humble about your understanding of the past.

This recognition and respect of the power of our minds to invent and love stories can help us reduce our misunderstanding of the world.

74. How (Supposedly) Rational People Make Decisions

There are four principles that Gregory Mankiw outlines in his multi-disciplinary economics textbook Principles of Economics.

I got the idea for reading an Economics textbook from Charlie Munger, the billionaire business partner of Warren Buffett. He said:

Economics was always more multidisciplinary than the rest of soft science. It just reached out and grabbed things as it needed to. And that tendency to just grab whatever you need from the rest of knowledge if you're an economist has reached a fairly high point in Mankiw's new textbook Principles of Economics. I checked out that textbook. I must have been one of the few businessmen in America that bought it immediately when it came out because it had gotten such a big advance. I wanted to figure out what the guy was doing where he could get an advance that great. So this is how I happened to riffle through Mankiw's freshman textbook. And there I found laid out as principles of economics: opportunity cost is a superpower, to be used by all people who have any hope of getting the right answer. Also, incentives are superpowers.

So we know that we can add Opportunity cost and incentives to our list of Mental Models. Let's dig in.

Principle 1: People Face Trade-offs

You have likely heard the old saying, "There is no such thing as a free lunch." There is much to this old adage and it's one we often forget when making decisions. To get more of something we like we almost always have to give up something else we like. A good heuristic in life is that if someone offers you something for nothing, turn it down.

Making decisions requires trading off one goal against another.

Consider a student who must decide how to allocate her most valuable resource—her time. She can spend all of her time studying economics, spend all of it studying psychology, or divide it between the two fields. For every hour she studies one subject, she gives up an hour she could have used studying the other. And for every hour she spends studying, she gives up an hour that she could have spent napping, bike riding, watching TV, or working at her part-time job for some extra spending money.

Or consider parents deciding how to spend their family income. They can buy food, clothing, or a family vacation. Or they can save some of the family income for retirement or for children's college education. When they choose to spend an extra dollar on one of these goods, they have one less dollar to spend on some other good.

These are rather simple examples but Mankiw offers some more complicated ones.

Consider the trade-off that society faces between efficiency and equality.

Efficiency means that society is getting the maximum benefits from its scarce resources.

Equality means that those benefits are distributed uniformly among society's members. In other words, efficiency refers to the size of the economic pie, and equality refers to how the pie is divided into individual slices.

When government policies are designed, these two goals often conflict. Consider, for instance, policies aimed at equalizing the distribution of economic well-being. Some of these policies, such as the welfare system or unemployment insurance, try to help the members of society who are most in need. Others, such as the individual income tax, ask the financially successful to contribute more than others to support the government. Though they achieve greater equality, these policies reduce efficiency. When the government redistributes income from the rich to the poor, it reduces the reward for working hard; as a result, people work less and produce fewer goods and services. In other words, when the government tries to cut the economic pie into more equal slices, the pie gets smaller.

Principle 2: The Cost of Something Is What You Give Up to Get It

Because of trade-offs, people face decisions between the costs and benefits of one course of action and the cost and benefits of another course. But costs are not as obvious as they might first appear — we need to apply some second-order thinking:

Consider the decision to go to college. The main benefits are intellectual enrichment and a lifetime of better job opportunities. But what are the costs? To answer this question, you might be tempted to add up the money you spend on tuition, books, room, and board. Yet this total does not truly represent what you give up to spend a year in college.

There are two problems with this calculation. First, it includes some things that are not really costs of going to college. Even if you quit school, you need a place to sleep and food to eat. Room and board are costs of going to college only to the extent that they are more expensive at college than elsewhere. Second, this calculation ignores the largest cost of going to college—your time. When you spend a year listening to lectures, reading textbooks, and writing papers, you cannot spend that time working at a job. For most students, the earnings they give up to attend school are the single largest cost of their education.

The opportunity cost of an item is what you give up to get that item. When making any decision, decision makers should be aware of the opportunity costs that accompany each possible action. In fact, they usually are. College athletes who can earn millions if they drop out of school and play professional sports are well aware that the opportunity cost of their attending college is very high. It is not surprising that they often decide that the benefit of a college education is not worth the cost.

Principle 3: Rational People Think at the Margin

For the sake of simplicity economists normally assume that people are rational. While this causes many problems, there is an undercurrent of truth to the fact that people systematically and purposefully “do the best they can to achieve their objectives, given opportunities.” There are two parts to rationality. The first is that your understanding of the world is correct. Second you maximize the use of your resources toward your goals.

Rational people know that decisions in life are rarely black and white but usually involve shades of gray. At dinnertime, the question you face is not “Should I fast or eat like a pig?” More likely, you will be asking yourself “Should I take that extra spoonful of mashed potatoes?” When exams roll around, your decision is not between blowing them off and studying twenty-four hours a day but whether to spend an extra hour reviewing your notes instead of watching TV. Economists use the term marginal change to describe a small incremental adjustment to an existing plan of action. Keep in mind that margin means “edge,” so marginal changes are adjustments around the edges of what you are doing. Rational people often make decisions by comparing marginal benefits and marginal costs. Thinking at the margin works for business decisions.

Consider an airline deciding how much to charge passengers who fly standby. Suppose that flying a 200-seat plane across the United States costs the airline \$100,000. In this case, the average cost of each seat is $\$100,000/200$, which is \$500. One might be tempted to conclude that the airline should never sell a ticket for less than \$500. But a rational airline can increase its profits by thinking at the margin. Imagine that a plane is about to take off with 10 empty seats and a standby passenger waiting at the gate is willing to pay \$300 for a seat. Should the airline sell the ticket? Of course, it should. If the plane has empty seats, the cost of adding one more passenger is tiny. The average cost of flying a passenger is \$500, but the marginal cost is merely the cost of the bag of peanuts and can of soda that the extra passenger will consume. As long as the standby passenger pays more than the marginal cost, selling the ticket is profitable.

This also helps answer the question of why diamonds are so expensive and water is so cheap.

Humans need water to survive, while diamonds are unnecessary; but for some reason, people are willing to pay much more for a diamond than for a cup of water. The reason is

that a person's willingness to pay for a good is based on the marginal benefit that an extra unit of the good would yield. The marginal benefit, in turn, depends on how many units a person already has. Water is essential, but the marginal benefit of an extra cup is small because water is plentiful. By contrast, no one needs diamonds to survive, but because diamonds are so rare, people consider the marginal benefit of an extra diamond to be large.

A rational decision maker takes an action if and only if the marginal benefit of the action exceeds the marginal cost.

Principle 4: People Respond to Incentives

Incentives induce people to act. If you use a rational approach to decision making that involves trade offs and comparing costs and benefits, you respond to incentives. Charlie Munger once said: "Never, ever, think about something else when you should be thinking about the power of incentives."

Incentives are crucial to analyzing how markets work. For example, when the price of an apple rises, people decide to eat fewer apples. At the same time, apple orchards decide to hire more workers and harvest more apples. In other words, a higher price in a market provides an incentive for buyers to consume less and an incentive for sellers to produce more. As we will see, the influence of prices on the behavior of consumers and producers is crucial for how a market economy allocates scarce resources.

Public policymakers should never forget about incentives: Many policies change the costs or benefits that people face and, as a result, alter their behavior. A tax on gasoline, for instance, encourages people to drive smaller, more fuel-efficient cars. That is one reason people drive smaller cars in Europe, where gasoline taxes are high, than in the United States, where gasoline taxes are low. A higher gasoline tax also encourages people to carpool, take public transportation, and live closer to where they work. If the tax were larger, more people would be driving hybrid cars, and if it were large enough, they would switch to electric cars.

75. A Few Useful Mental Tools from Richard Feynman

We've covered the brilliant physicist Richard Feynman (1918-1988) many times here before. He was a genius. A true genius. But there have been many geniuses — physics has been fortunate to attract some of them — and few of them are as well known as Feynman. Why is Feynman so well known? It's likely because he had tremendous range *outside* of pure science, and although he won a Nobel Prize for his work in quantum mechanics, he's probably best known for other things, primarily his wonderful ability to explain and teach.

This ability was on display in a series of non-technical lectures in 1963, memorialized in a short book called The Meaning of it All: Thoughts of a Citizen Scientist. The lectures are a wonderful example of how well Feynman's brain worked *outside* of physics, talking through basic reasoning and some of the problems of his day.

Particularly useful are a series of "tricks of the trade" he gives in a section called *This Unscientific Age*. These tricks show Feynman taking the method of thought he learned in pure science and applying it to the more mundane topics most of us have to deal with every day. They're wonderfully instructive. Let's check them out.

Before we start, it's worth noting that Feynman takes pains to mention that not everything needs to be considered with scientific accuracy. So don't waste your time unless it's a scientific matter. So let's start with a deep breath:

Now, that there are unscientific things is not my grief. That's a nice word. I mean, that is not what I am worrying about, that there are unscientific things. That something is unscientific is not bad; there is nothing the matter with it. It is just unscientific. And scientific is limited, of course, to those things that we can tell about by trial and error. For example, there is the absurdity of the young these days chanting things about purple people eaters and hound dogs, something that we cannot criticize at all if we belong to the old flat foot floogie and a floy floy or the music goes down and around. Sons of mothers who sang about "come, Josephine, in my flying machine," which sounds just about as modern as "I'd like to get you on a slow boat to China." So in life, in gaiety, in emotion, in human pleasures and pursuits, and in literature and so on, there is no need to be scientific, there is no reason to be scientific. One must relax and enjoy life. That is not the criticism. That is not the point.

As we enter the realm of "knowable" things in a scientific sense, the first trick has to do with deciding whether someone truly knows their stuff or is mimicking:

The first one has to do with whether a man knows what he is talking about, whether what he says has some basis or not. And my trick that I use is very easy. If you ask him intelligent questions—that is, penetrating, interested, honest, frank, direct questions on the subject, and no trick questions—then he quickly gets stuck. It is like a child asking naive questions. If you ask naive but relevant questions, then almost immediately the person doesn't know the answer, if he is an honest man. It is important to appreciate that.

And I think that I can illustrate one unscientific aspect of the world which would be probably very much better if it were more scientific. It has to do with politics. Suppose two politicians are running for president, and one goes through the farm section and is asked, "What are you going to do about the farm question?" And he knows right away— bang, bang, bang.

Now he goes to the next campaigner who comes through. "What are you going to do about the farm problem?" "Well, I don't know. I used to be a general, and I don't know anything about farming. But it seems to me it must be a very difficult problem, because for twelve, fifteen, twenty years people have been struggling with it, and people say that they know how to solve the farm problem. And it must be a hard problem. So the way that I intend to solve the farm problem is to gather around me a lot of people who know something about it, to look at all the experience that we have had with this problem before, to take a certain

amount of time at it, and then to come to some conclusion in a reasonable way about it. Now, I can't tell you ahead of time what conclusion, but I can give you some of the principles I'll try to use—not to make things difficult for individual farmers, if there are any special problems we will have to have some way to take care of them,” etc., etc., etc. That's a wonderfully useful way to figure out whether someone is Max Planck or the chauffeur.

The second trick regards how to deal with uncertainty:

People say to me, “Well, how can you teach your children what is right and wrong if you don't know?” Because I'm pretty sure of what's right and wrong. I'm not absolutely sure; some experiences may change my mind. But I know what I would expect to teach them. But, of course, a child won't learn what you teach him.

I would like to mention a somewhat technical idea, but it's the way, you see, we have to understand how to handle uncertainty. How does something move from being almost certainly false to being almost certainly true? How does experience change? How do you handle the changes of your certainty with experience? And it's rather complicated, technically, but I'll give a rather simple, idealized example.

You have, we suppose, two theories about the way something is going to happen, which I will call “Theory A” and “Theory B.” Now it gets complicated. Theory A and Theory B. Before you make any observations, for some reason or other, that is, your past experiences and other observations and intuition and so on, suppose that you are very much more certain of Theory A than of Theory B—much more sure. But suppose that the thing that you are going to observe is a test. According to Theory A, nothing should happen. According to Theory B, it should turn blue. Well, you make the observation, and it turns sort of a greenish. Then you look at Theory A, and you say, “It's very unlikely,” and you turn to Theory B, and you say, “Well, it should have turned sort of blue, but it wasn't impossible that it should turn sort of greenish color.” So the result of this observation, then, is that Theory A is getting weaker, and Theory B is getting stronger. And if you continue to make more tests, then the odds on Theory B increase. Incidentally, it is not right to simply repeat the same test over and over and over and over, no matter how many times you look and it still looks greenish, you haven't made up your mind yet. But if you find a whole lot of other things that distinguish Theory A from Theory B that are different, then by accumulating a large number of these, the odds on Theory B increase.

Feynman is talking about Grey Thinking here, the ability to put things on a gradient from “probably true” to “probably false” and how we deal with that uncertainty. He isn't proposing a method of figuring out absolute, doctrinaire truth.

Another term for what he's proposing is Bayesian updating — starting with a priori odds, based on earlier understanding, and “updating” the odds of something based on what you learn thereafter. An extremely useful tool.

Feynman's third trick is the realization that as we investigate whether something is true or not, new evidence and new methods of experimentation should show the effect of getting *stronger and stronger, not weaker*. He uses an excellent example here by analyzing mental telepathy:

I give an example. A professor, I think somewhere in Virginia, has done a lot of experiments for a number of years on the subject of mental telepathy, the same kind of stuff as mind reading. In his early experiments the game was to have a set of cards with various designs on them (you probably know all this, because they sold the cards and people used to play this game), and you would guess whether it's a circle or a triangle and so on while someone else was thinking about it. You would sit and not see the card, and he would see the card and think about the card and you'd guess what it was. And in the beginning of these researches, he found very remarkable effects. He found people who would guess ten to fifteen of the cards correctly, when it should be on the average only

five. More even than that. There were some who would come very close to a hundred percent in going through all the cards. Excellent mind readers.

A number of people pointed out a set of criticisms. One thing, for example, is that he didn't count all the cases that didn't work. And he just took the few that did, and then you can't do statistics anymore. And then there were a large number of apparent clues by which signals inadvertently, or advertently, were being transmitted from one to the other.

Various criticisms of the techniques and the statistical methods were made by people. The technique was therefore improved. The result was that, although five cards should be the average, it averaged about six and a half cards over a large number of tests. Never did he get anything like ten or fifteen or twenty-five cards. Therefore, the phenomenon is that the first experiments are wrong. The second experiments proved that the phenomenon observed in the first experiment was nonexistent. The fact that we have six and a half instead of five on the average now brings up a new possibility, that there is such a thing as mental telepathy, but at a much lower level. It's a different idea, because, if the thing was really there before, having improved the methods of experiment, the phenomenon would still be there. It would still be fifteen cards. Why is it down to six and a half? Because the technique improved. Now it still is that the six and a half is a little bit higher than the average of statistics, and various people criticized it more subtly and noticed a couple of other slight effects which might account for the results.

It turned out that people would get tired during the tests, according to the professor. The evidence showed that they were getting a little bit lower on the average number of agreements. Well, if you take out the cases that are low, the laws of statistics don't work, and the average is a little higher than the five, and so on. So if the man was tired, the last two or three were thrown away. Things of this nature were improved still further. The results were that mental telepathy still exists, but this time at 5.1 on the average, and therefore all the experiments which indicated 6.5 were false. Now what about the five? . . . Well, we can go on forever, but the point is that there are always errors in experiments that are subtle and unknown. But the reason that I do not believe that the researchers in mental telepathy have led to a demonstration of its existence is that as the techniques were improved, the phenomenon got weaker. In short, the later experiments in every case disproved all the results of the former experiments. If remembered that way, then you can appreciate the situation.

This echoes Feynman's dictum about not fooling oneself: We must refine our process for probing and experimenting if we're to get at real truth, always watching out for little troubles. Otherwise, we torture the world so that results fit our expectations. If we carefully refine and re-test and the effect gets weaker all the time, it's likely to not be true, or at least not to the magnitude originally hoped for.

The fourth trick is to ask *the right question*, which is not "Could this be the case?" but "Is this *actually* the case?" Many get so caught up with the former that they forget to ask the latter:

That brings me to the fourth kind of attitude toward ideas, and that is that the problem is not what is possible. That's not the problem. The problem is what is probable, what is happening. It does no good to demonstrate again and again that you can't disprove that this could be a flying saucer. We have to guess ahead of time whether we have to worry about the Martian invasion. We have to make a judgment about whether it is a flying saucer, whether it's reasonable, whether it's likely. And we do that on the basis of a lot more experience than whether it's just possible, because the number of things that are possible is not fully appreciated by the average individual. And it is also not clear, then, to them how many things that are possible must not be happening. That it's impossible that everything that is possible is happening. And there is too much variety, so most likely anything that you think of that is possible isn't true. In fact that's a general principle in physics theories: no matter what a guy thinks of, it's almost always false. So there have

been five or ten theories that have been right in the history of physics, and those are the ones we want. But that doesn't mean that everything's false. We'll find out.

The fifth trick is a very, very common one, even 50 years after Feynman pointed it out. You cannot judge the probability of something happening *after it's already happened*. That's cherry-picking. You have to run the experiment *forward* for it to mean anything:

I now turn to another kind of principle or idea, and that is that there is no sense in calculating the probability or the chance that something happens after it happens. A lot of scientists don't even appreciate this. In fact, the first time I got into an argument over this was when I was a graduate student at Princeton, and there was a guy in the psychology department who was running rat races. I mean, he has a T-shaped thing, and the rats go, and they go to the right, and the left, and so on. And it's a general principle of psychologists that in these tests they arrange so that the odds that the things that happen happen by chance is small, in fact, less than one in twenty. That means that one in twenty of their laws is probably wrong. But the statistical ways of calculating the odds, like coin flipping if the rats were to go randomly right and left, are easy to work out.

This man had designed an experiment which would show something which I do not remember, if the rats always went to the right, let's say. I can't remember exactly. He had to do a great number of tests, because, of course, they could go to the right accidentally, so to get it down to one in twenty by odds, he had to do a number of them. And it's hard to do, and he did his number. Then he found that it didn't work. They went to the right, and they went to the left, and so on. And then he noticed, most remarkably, that they alternated, first right, then left, then right, then left. And then he ran to me, and he said, "Calculate the probability for me that they should alternate, so that I can see if it is less than one in twenty." I said, "It probably is less than one in twenty, but it doesn't count." He said, "Why?" I said, "Because it doesn't make any sense to calculate after the event. You see, you found the peculiarity, and so you selected the peculiar case."

For example, I had the most remarkable experience this evening. While coming in here, I saw license plate ANZ 912. Calculate for me, please, the odds that of all the license plates in the state of Washington I should happen to see ANZ 912. Well, it's a ridiculous thing. And, in the same way, what he must do is this: The fact that the rat directions alternate suggests the possibility that rats alternate. If he wants to test this hypothesis, one in twenty, he cannot do it from the same data that gave him the clue. He must do another experiment all over again and then see if they alternate. He did, and it didn't work.

The sixth trick is one that's familiar to almost all of us, yet almost all of us forget about every day: *The plural of anecdote is not data*. We must use proper statistical sampling to know whether or not we know what we're talking about:

The next kind of technique that's involved is statistical sampling. I referred to that idea when I said they tried to arrange things so that they had one in twenty odds. The whole subject of statistical sampling is somewhat mathematical, and I won't go into the details. The general idea is kind of obvious. If you want to know how many people are taller than six feet tall, then you just pick people out at random, and you see that maybe forty of them are more than six feet so you guess that maybe everybody is. Sounds stupid.

Well, it is and it isn't. If you pick the hundred out by seeing which ones come through a low door, you're going to get it wrong. If you pick the hundred out by looking at your friends you'll get it wrong because they're all in one place in the country. But if you pick out a way that as far as anybody can figure out has no connection with their height at all, then if you find forty out of a hundred, then, in a hundred million there will be more or less forty million. How much more or how much less can be worked out quite accurately. In fact, it turns out that to be more or less correct to 1 percent, you have to have 10,000 samples. People don't realize how difficult it is to get the accuracy high. For only 1 or 2 percent you need 10,000 tries.

The last trick is to realize that many errors people make simply come from *lack of information*. They don't even know they're missing the tools they need. This can be a very tough one to guard against — it's hard to know when you're missing information that would change your mind — but Feynman gives the simple case of astrology to prove the point: *Now, looking at the troubles that we have with all the unscientific and peculiar things in the world, there are a number of them which cannot be associated with difficulties in how to think, I think, but are just due to some lack of information. In particular, there are believers in astrology, of which, no doubt, there are a number here. Astrologists say that there are days when it's better to go to the dentist than other days. There are days when it's better to fly in an airplane, for you, if you are born on such a day and such and such an hour. And it's all calculated by very careful rules in terms of the position of the stars. If it were true it would be very interesting. Insurance people would be very interested to change the insurance rates on people if they follow the astrological rules, because they have a better chance when they are in the airplane. Tests to determine whether people who go on the day that they are not supposed to go are worse off or not have never been made by the astrologers. The question of whether it's a good day for business or a bad day for business has never been established. Now what of it? Maybe it's still true, yes. On the other hand, there's an awful lot of information that indicates that it isn't true. Because we have a lot of knowledge about how things work, what people are, what the world is, what those stars are, what the planets are that you are looking at, what makes them go around more or less, where they're going to be in the next 2000 years is completely known. They don't have to look up to find out where it is. And furthermore, if you look very carefully at the different astrologers they don't agree with each other, so what are you going to do? Disbelieve it. There's no evidence at all for it. It's pure nonsense. The only way you can believe it is to have a general lack of information about the stars and the world and what the rest of the things look like. If such a phenomenon existed it would be most remarkable, in the face of all the other phenomena that exist, and unless someone can demonstrate it to you with a real experiment, with a real test, took people who believe and people who didn't believe and made a test, and so on, then there's no point in listening to them.*

76. Daniel Dennett's Most Useful Critical Thinking Tools

We recently discussed some wonderful mental tools from the great Richard Feynman.

Let's get some more good ones from another giant, Daniel Dennett.

Dennett is one of the great thinkers in the world; he's been at the forefront of cognitive science and evolutionary science for over 50 years, trying to figure out how the mind works and why we believe the things we believe. He's written a number of amazing books on evolution, religion, consciousness, and free will. (He's also subject to some extreme criticism due to his atheist bent, as with Dawkins.)

His most recent book is the wise and insightful Intuition Pumps and Other Tools for Critical Thinking, where he lays out a series of short essays (some very short — less than a page) with mental shortcuts, tools, analogies, and metaphors for thinking about a variety of topics, mostly those topics he is best known for.

Some people don't like the disconnected nature of the book, but that's precisely its usefulness: Like what we do here at Farnam Street, Dennett is simply trying to add tools to your toolkit. You are free to, in the words of Bruce Lee, "*Absorb what is useful, discard what is useless and add what is specifically your own.*"

The book opens with 12 of Dennett's best "tools for critical thinking" — a bag of mental tricks to improve your ability to engage critically and rationally with the world.

Let's go through a few of the best ones. You'll be familiar with some and unfamiliar with others, agree with some and not with others. But if you adopt Bruce Lee's advice, you should come away with something new and useful.

Making mistakes

Mistakes are not just opportunities for learning; they are, in an important sense, the only opportunity for learning or making something truly new. Before there can be learning, there must be learners. There are only two non-miraculous ways for learners to come into existence: they must either evolve or be designed and built by learners that evolved. Biological evolution proceeds by a grand, inexorable process of trial and error—and without the errors the trials wouldn't accomplish anything. As Gore Vidal once said, "It is not enough to succeed. Others must fail."

[...]

The chief trick to making good mistakes is not to hide them—especially not from yourself. Instead of turning away in denial when you make a mistake, you should become a connoisseur of your own mistakes, turning them over in your mind as if they were works of art, which in a way they are. The fundamental reaction to any mistake ought to be this: "Well, I won't do that again!"

Reductio ad absurdum

The crowbar of rational inquiry, the great lever that enforces consistency, is reductio ad absurdum—literally, reduction (of the argument) to absurdity. You take the assertion or conjecture at issue and see if you can pry any contradictions (or just preposterous implications) out of it. If you can, that proposition has to be discarded or sent back to the shop for retooling. We do this all the time without bothering to display the underlying logic: "If that's a bear, then bears have antlers!" or "He won't get here in time for supper unless he can fly like Superman."

Rapoport's Rules

Just how charitable are you supposed to be when criticizing the views of an opponent? [...] The best antidote I know for [the] tendency to caricature one's opponent is a list of rules promulgated by the social psychologist and game theorist Anatol Rapoport (creator of the winning Tit-for-Tat strategy in Robert Axelrod's legendary prisoner's dilemma tournament). How to compose a successful critical commentary:

1. You should attempt to re-express your target's position so clearly, vividly, and fairly that your target says, "Thanks, I wish I'd thought of putting it that way."
2. You should list any points of agreement (especially if they are not matters of general or widespread agreement).
3. You should mention anything that you have learned from your target.
4. Only then are you permitted to say so much as a word of rebuttal or criticism.

Sturgeon's Law

The science-fiction writer Ted Sturgeon, speaking at the World Science Fiction Convention in Philadelphia in September 1953, said,

When people talk about the mystery novel, they mentioned The Maltese Falcon and The Big Sleep. When they talk about the western, they say there's The Way West and Shane. But when they talk about science fiction, they call it "that Buck Rogers stuff," and they say "ninety percent of science fiction is crud." Well, they're right. Ninety percent of science fiction is crud. But then ninety percent of everything is crud, and it's the ten percent that isn't crud that's important, and the ten percent of science fiction that isn't crud is as good as or better than anything being written anywhere.

This advice is often ignored by ideologues intent on destroying the reputation of analytic philosophy, evolutionary psychology, sociology, cultural anthropology, macroeconomics, plastic surgery, improvisational theater, television sitcoms, philosophical theology, massage therapy, you name it. Let's stipulate at the outset that there is a great deal of deplorable, stupid, second-rate stuff out there, of all sorts.

Occam's Razor

*Attributed to William of Ockham (or Occam), the fourteenth century logician and philosopher, this thinking tool is actually a much older rule of thumb. A Latin name for it is *lex parsimoniae*, the law of parsimony. It is usually put into English as the maxim "Do not multiply entities beyond necessary." The idea is straightforward: Don't concoct a complicated, extravagant theory if you've got a simpler one (containing fewer ingredients, fewer entities) that handles the phenomenon just as well. If exposure to extremely cold air can account for all the symptoms of frostbite, don't postulate unobserved "snow germs" or "arctic microbes." Kepler's laws explain the orbit of the planets; we have no need to hypothesize pilots guiding the planets from control panels hidden under the surface.*

Occam's Broom

The molecular biologist Sidney Brenner recently invented a delicious play on Occam's Razor, introducing the new term Occam's Broom, to describe the process in which inconvenient facts are whisked under the rug by intellectually dishonest champions of one theory or another. This is our first boom crutch, an anti-thinking tool, and you should keep your eyes peeled for it. The practice is particularly insidious when used by propagandists who direct their efforts at the lay public, because like Sherlock Holmes' famous clue about the dog that didn't bark in the night, the absence of a fact that has been swept off the scene by Occam's Broom is unnoticeable except by experts.

Jootsing

...It is even harder to achieve what Doug Hofstadter calls jooisting, which stands for "jumping out of the system." This is an important tactic not just in science and philosophy, but also in the arts. Creativity, that ardently sought but only rarely found virtue, often is a heretofore unimagined violation of the rules of the system from which it springs. It might be the system of classical harmony in music, the rules for meter and rhyme in sonnets (or limericks, even), or the canons of good taste or good form in some genre of art. Or it might be the assumptions and principles of some theory or research program. Being creative is not just a matter of casting about for something novel—anybody can do that, since novelty can be found in any random juxtaposition of stuff—but of making the novelty jump out of some system, a system that has become somewhat established, for good reasons.

When an artistic tradition reaches the point where literally “anything goes,” those who want to be creative have a problem: there are no fixed rules to rebel against, no complacent expectations to shatter, nothing to subvert, no background against which to create something that is both surprising and yet meaningful. It helps to know the tradition if you want to subvert it. That’s why so few dabblers or novices succeed in coming up with anything truly creative.

Rathering (Anti-thinking tool)

Rathering is a way of sliding you swiftly and gently past a false dichotomy. The general form of a rathering is “It is not the case that blahblahblah, as orthodoxy would have you believe; it is rather that suchandsuchandsuch—which is radically different.” Some ratherings are just fine; you really must choose between the two alternatives on offer; in these cases, you are not being offered a false, but rather a genuine, inescapable dichotomy. But some ratherings are little more than sleight of hand, due to the fact that the word “rather” implies—without argument—that there is an important incompatibility between the claims flanking it.

The “Surely” Operator

When you’re reading or skimming argumentative essays, especially by philosophers, here is a quick trick that may save you much time and effort, especially in this age of simple searching by computer: look for “surely” in the document, and check each occurrence. Not always, not even most of the time, but often the word “surely” is as good as a blinking light in locating a weak point in the argument.... Why? Because it marks the very edge of what the author is actually sure about and hopes readers will also be sure about. (If the author were really sure all the readers would agree, it wouldn’t be worth mentioning.)

The Deepity

A “deepity” is a proposition that seems both important and true—and profound—but that achieves this effect by being ambiguous. On one reading it is manifestly false, but it would be earth-shaking if it were true; on the other reading it is true but trivial. The unwary listener picks up on the glimmer of truth from the second reading, and the devastating importance from the first reading, and thinks, Wow! That’s a deepity.

Here is an example. (Better sit down: this is heavy stuff.)

Love is just a word.

[...]

*Richard Dawkins recently alerted me to a fine deepity by Rowan Williams, the Archbishop of Canterbury, who described his faith as a
silent waiting on the truth, pure sitting and breathing in the presence of a question mark.*

77. Mental Models: Getting the World to Do the Work for You

People are working harder and harder to clean up otherwise avoidable messes they created by making poor initial decisions. There are many reasons we're making poor decisions and failing to learn from them.

Under the heading, Sources of Stupidity in an article entitled Smart Decisions we wrote about some of the factors that contribute to suboptimal decisions.

1. *We're (sometimes) stupid. Of course, I like to think that I'm rational and capable of interpreting all of the information in a non-biased way. Only I'm not. At least not always. There are situations that increase the odds of irrationality, for instance when we're tired, overly focused on a goal, rushing, distracted or interrupted, operating in a group, or are under the direction of an expert*².

2. *We have the wrong information. In this case, we're operating with the wrong facts or our assumptions are incorrect.*

3. *We use the wrong model. We use models to make decisions. The quality of those models often determines the quality of our thinking. There are a variety of reasons that we use false, incomplete, or incorrect models. For instance, we're prone to using less useful models when we are a novice or we operate in a domain outside of our area of expertise. The odds of the wrong model also increase as the pace of environmental change increases.*

4. *We fail to learn. We all know the person that has 20 years of experience but it's really the same year over and over. Well, that person is sometimes us. If we don't understand how we learn, we're likely to make the same mistakes over and over.*

5. *Doing what's easy over what's right. You can think of this as looking good over doing good. In this case, we make choices based on optics, explainability, politics, etc. Mostly this comes from not having a strong sense of self and seeking external validation or avoiding punishment.*

Simple But Not Easy

One of the metamodels that traverse all five of these sources of stupidity is understanding the world.

If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.

Understanding The World

How can we best understand the world as it is?

Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer.

If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.

This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models.

Mental models are a framework for understanding how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your

perspective with ease. Mental Models allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise?

Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right?

We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

2nd Order Thinking

One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself "If I do X, what will happen *after* that?". I sum this up using the ecologist Garrett Hardin's simple question:

"And then what?"

A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it.

We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves "And then what?" We don't ask what other solutions might be even *more* optimal.

For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve. Optically, they "reorganize their incentive programs," but practically, they've simply expended energy to stay in place.

Another, perhaps more complicated, example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He's got all these beautiful charts on how much more competitive you'll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You're sold.

Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitor's door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins.

We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn't always a comfortable reality.

Understanding how the world works isn't easy and it shouldn't be. It's hard work. If it were easy, everyone would do it. And it's not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and

becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it's extremely helpful to understand the forces at play outside of their narrow area of expertise.

Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

78. Mental Model: Bias from Envy and Jealousy

*"It is not greed that drives the world,
but envy."*

— Warren Buffett

It is a fact of life that we are not equal. Not biologically, not culturally.

Some inequities come from flawed governing systems, but most are simply due to luck — the vagaries of life. Some of us are born healthier, prettier and smarter than others, some will encounter opportunities to become extremely wealthy, and some will simply be born at the right place and time. Just as many will be born without such good fortune.

It's difficult to imagine that these differences will not matter in our everyday interactions.

When you think of how natural the differences among us are, you should quickly come to realize the potential power and frequency that bias from envy and jealousy can have on world affairs. It's built deeply into the human condition, from birth.

The concept of jealousy is as old as modern humanity itself and has permeated our culture worldwide. We are advised not to brag too much, for it can evoke feelings of envy and jealousy in others. Christianity, Hinduism, Islam and other religions all have at least one cautionary tale about the destructive consequences of being captivated by these emotions as well as the dangers of being the one who is envied.

The stoics knew all about envy, and warned against its consequences

constantly. Seneca described a wise man as one who is *"Content with his lot, whatever it be, without wishing for what he has not ..."*

Tales of envy extend as far back as ancient times.

In one of the oldest recorded myths, the tall, slender and handsome Egyptian

God Osiris marries his beautiful sister and brings civilization and prosperity to Egypt and the world. However, Osiris also has an ugly younger brother Seth who hates him. Seth envies Osiris for his attractiveness, power and success. Seth's wife becomes so attracted to Osiris that she tricks him into sleeping with her and bears Osiris's child. Unable to deal with his envy and jealousy, Seth traps and kills Osiris.

Even though the myth is several thousand years old, the problems caused by envy and jealousy can be just as real and destructive today. To avoid these feelings and becoming a victim of them is an important reason to examine them a little closer.

The Two Types of Envy

It has been said that there are two types of envy – a good type and a bad type.

The first type is the feeling of inferiority that motivates a person to improve herself.

This bias exerts its influence by framing the success of others as a learning opportunity for ourselves. Think about watching an inspirational movie, or reading a book about an inspirational figure, someone who you feel dwarfs your own capabilities and accomplishments. Frequently, our envy leads us to imitate that hero in a quest for self-improvement.

The other type, though, is malicious envy, which motivates the envious to take good things away from others. For Aristotle, the evil of malicious envy lay in its desire to lessen the good in the world and experience joy at another's misfortune (also

called *Schadenfreude* which, mysteriously enough, has no equivalent word in English.)

To the malicious envier, ridding oneself of envy requires taking away from the other — the beautiful car or house should be stolen or damaged, the virtuous person corrupted or killed and the beautiful face of someone ruined or covered. The malicious envier believes that those things should be *his* rather than *theirs*. He, after all, deserves it more.

Lord Chesterfield once said: *"People hate those who make them feel their own inferiority."*

This can be true. While the envied need not cause the deprivation of the other, the envier may still experience anger or resentment, a sense of unfairness, which may lead to

feelings of hate. The relation between envy and hate is pretty close, if you observe the world closely.

“Envy is pain at the good fortune of others.

We envy those who are near us in time, place, age or reputation.”

— Aristotle

There are two basic determinants of the type of envy that will be experienced: *the degree of belief that one has been treated unfairly and the belief that one's disadvantage is one's own fault.*

Common sense, and data presented by Peter Salovey in his book The Psychology of Envy and Jealousy, suggest that the second determinant, one's belief in one's own shortcomings, plants the motivation for improvement.

The belief that one has been treated unfairly has the opposite effect – it results in feelings of anger and resentment. You become a negatively coiled spring.

Social Comparison

“Injustice is relatively easy to bear, it is justice that hurts.”

— Henry Louis Mencken

At the heart of envy is social comparison, which is a powerful influence in our self-concept. Think about it – much of our self-definition comes from comparison with others. We can't define ourselves as great singers, if there is no one else around who sings worse than we do. Qualities like intelligence, beauty and skills are relative and thus when we compare poorly in comparison to our peers, our self-esteem suffers. Judith Rich Harris argues that this is a core part of our personality development.

An inflamed self-esteem is a good first step towards envy. We experience envy when the quality we feel inferior about threatens our self-concept. We may not even be aware that we are lacking a particular quality, but the object of our envy heightens our awareness of our deprivation.

Think about it this way: Do you feel envy when you see a great javelin thrower at the Olympics? Probably not, because, for most of us, success at javelin throwing isn't a core part of our self-concept. But let's say you were a competitive javelin thrower — might you feel a little envy if you saw someone much better than you competing at the Olympics? Thus, envy of others is always a reflection of something we feel about *ourselves*. We're not rich enough, or smart enough, or beautiful enough; we don't have enough possessions, enough attention, enough success.

Jealousy

If there is a way to define jealousy in its most narrow scope, then it would probably be the feeling of anxious insecurity that follows the perception of threat to a relationship which provides important attention. Perceiving such a threat makes a person feel insecure about the status of the relationship and thus also about the aspects of the self that are sustained by it.

We do not become jealous when our partners die or move across the country or quit the relationship without getting into a new one. What is always true for jealousy, unlike envy, is that it involves a triangle of relationships between the self, the partner and the rival.

Therefore, when talking about jealousy it is important to realize its key characteristic — the threat of losing something to *someone else*.

There is the hypothesis that at the heart of feelings of jealousy lies our need to feel needed. This need exists because relationships define certain aspects of who we are.

We like to think of ourselves as sexually attractive, funny or otherwise worthy persons.

However, when there is no one to be funny with or no one who is attracted to us, our self-definition of *funny* or *attractive* dissipates. We need the others not only to reaffirm these aspects, but also to *create* them. Humans are deeply social creatures — how we feel about ourselves has to do with our interactions with others. There are no personality traits in a vacuum.

Jealousy is not limited to romantic relationships — jealousy exists between siblings, co-workers and even friends. Yet there is a reason why we get so caught up in romantic jealousy.

Someone stealing away our chess partner's time does not threaten our self-concept nearly as much someone stealing away our girlfriend's time. We have a biological need for a romantic other that eclipses our need for a chess partner; feelings of deprivation are intensified.

Children can also experience intense jealousy. The most important relationship for a child is that with his parents, which is why sibling rivalry can sometimes be so fierce. Naturally, as the child reaches adolescence and develops serious friendships and romantic relationships, the sibling jealousy tends to dissipate.

There are several notable commonalities and differences between *jealousy* and *envy*. With both envy and jealousy we experience loss of self-esteem stemming from social comparison. In the case of envy the loss comes from our self-appraisal, whereas in the case of jealousy it comes from the appraisal by others. Therefore, when experiencing jealousy we are often left wondering *what is it that the other person finds in our rival?* whereas in the case of envy we know exactly what we're missing.

Another common quality of both envy and jealousy is how extreme they can be in modern life. For instance, ongoing discussions about employee salaries and CEO salaries. In many workplaces this has resulted in a salary non-disclosure policy within the job contract. Still, when the compensation data is leaked, and some perceived inequality is discovered, there is often outrage.

These effects are observed in workplaces as diverse as universities, investment banks, corporates and law firms. In order to keep the air clear of envy and jealousy, numerous firms and government agencies have gone as far as opting for the same base compensation per seniority level, regardless of employee contribution. Berkshire Hathaway chooses not to disclose the compensation of most of its top people for fear of creating organization-wide envy, and CEO Warren Buffett credits his ridiculously low salary with keeping envy of his success to a minimum.

An important question remains: How should we deal with envy at a personal level?

There are three ways to overcome envy.

The first is to focus on the differences between you and the other person, rather than the similarities. Examine the situation — you are not as alike as you think you are.

The second is more difficult, but we certainly find we can do it in other contexts, as discussed above. Shape your malicious envy into a drive to improve and learn. From every person that we envy there is a virtue that we can learn from.

Thirdly, envy can be avoided (over time) with simple repetitive denial. Don't let yourself become envious of others' deserved success. Stop the feeling in its tracks, if you can. As for *undeserved* success, remind yourself that the world is not a fair place that owes us what we wish. Remind yourself that the success of others does not reflect on you and does not take away from you. Envy is a somewhat childish emotion, one that hurts us as we get older.

Jealousy is more difficult to overcome since we are not fully in control of the needs or perceptions of others. There is little we can do to make others appreciate us when they don't, but we can learn to accept that we will not always be everything for everyone. Just as with envy — jealousy can be an important trigger for increased self-awareness as well as positive change. After all, a little jealousy can be a good thing, for we may be reminded to appreciate what we have.

The sins of jealousy and envy drive huge swaths of human behavior, but if we work to understand it and see it in ourselves and others, it doesn't have to drive ours.

*“Man will do many things to get himself loved;
he will do all things to get himself envied.”*

— Mark Twain

Envy is a great cause of human suffering. Charlie Munger points out why: “Envy is a really stupid sin because it’s the only one you could never possibly have any fun at. There’s a lot of pain and no fun. Why would you want to get on that trolley?”

Why indeed.

While envy and jealousy are powerful drivers of behaviour on their own, they become more powerful when mixed with ego, greed, and fear. These emotions can weigh the mind down and dramatically diminish our ability to think with our full mental capacity. They can also hone our focus. These emotions have also motivated people to do great things.

And in case you’re wondering how you can avoid being the source of envy for others?

Aristotle had an answer: “The best way to avoid envy is to deserve the success you get.”

79. Multiplicative Systems: Understanding The Power of Multiplying by Zero

We all learned in math class that anything times zero is zero. But if you stop thinking about the idea here, you don't see all the practical applications that understanding multiplicative systems can give you in life.

Let's run through a little elementary algebra. Try to do it in your head: What's $1,506,789 \times 9,809 \times 5.56 \times 0$?

Hopefully, you didn't have to whip out the old TI-84 to solve that one. It's a zero.

This leads us to a mental model called Multiplicative Systems and understanding it can get to the heart of a lot of issues.

The Weakest Link in the Chain

Suppose you were trying to become the best basketball player in the world. You've got the following things going for you:

1. God-given talent. You're 6'9", quick, skillful, can leap out of the building, and have been the best player in a competitive city since you can remember.
2. Support. You live in a city that reveres basketball and you're raised by parents who care about your goals.
3. A proven track record. You were the player of the year in a very competitive Division 1 college conference.
4. A clear path forward. You're selected as the second overall pick in the NBA Draft by the Boston Celtics.

Sounds like you have a shot, right? As good as anyone could have, right? What would you put the odds at of this person becoming one of the better players in the world? Pretty high?

Let's add one more piece of information:

5. You've developed a cocaine habit.

What are your odds now?

This little exercise isn't an academic one, it's the sad case of Leonard "Len" Bias, a young basketball prodigy who died of a cocaine overdose after being selected to play in the NBA for the Boston Celtics in 1986. Many call Bias the best basketball player who never played professionally.

What the story of Len Bias illustrates so well is the truth that anything times zero must still be zero, no matter how large the string of numbers preceding it. In some facets of life, all of your hard work, dedication to improvement, and good fortune may still be worth nothing if there is a weak link in the chain.

Something all engineers learn very early on is that a system is no stronger than its weakest component. Take, for example, the case of a nuclear power plant. We have a very good understanding of how to make the nuclear power plant quite safe, nearly indestructible, which it must be considering the magnitude of a failure.

But in reality, what is the weakest link in the chain for most nuclear power plants? *The human beings running them.* We're part of the system! And since we've yet to perfect the human being, we have yet to perfect the nuclear power plant. How could it be otherwise?

An additive system does not work this way. In an additive system, each component adds on to one another to create the final outcome. Going back to algebra, let's say our equation was additive rather than

multiplicative: $1,506,789 \text{ plus } 9,809 \text{ plus } 5.56 \text{ plus } 0$. The answer is 1,516,603.56 — still a pretty big number!

Think of an additive system as something like a great Thanksgiving dinner. You've got a great turkey, some whipped potatoes, a mass of stuffing, and a lump of homemade cranberry sauce, and you're hanging with your family. Awesome!

Let's say the potatoes get burnt in the oven, and they're inedible. Problem? Sure, but dinner still works out just fine. Someone shows up with a pie for dessert? Great! But it won't change the dinner all that much.

The interaction of the parts makes the dinner range from good to great. Take some parts away or add new ones in, and you get a different outcome, but not a *binary*, win/lose one. The meal still happens. Additive systems and multiplicative systems react differently when components are added or taken away.

Most businesses, for example, operate in a multiplicative system. But they too often *think* they're operating in additive ones: Ever notice how some businesses will add one feature on top of another to their products but fail at basic customer service, so you leave, never to return? That's a business that thinks it's in an additive system when they really need to be resolving the big fat *zero* in the middle of the equation instead of adding more stuff.

Financial systems are, of course, multiplicative. General Motors, founded in 1908 by William Durant and C.S. Mott, came to dominate the American car market to the tune of 50% market share through a series of brilliant innovations and management practices and was for many years the dominant and most admirable corporation in America. Even today, after more than a century of competition, no American carmaker produces more automobiles than General Motors.

And yet, the original shareholders of GM ended up with a *zero* in 2008 as the company went into bankruptcy due to years of financial mismanagement. It didn't matter that they had several generations of leadership: All of that becomes naught in a multiplicative system.

On a smaller scale, take the case of a young corporate climber who feels they just can't get ahead. They seem to have all their ducks in a row: great resume, great background, great experience...the problem is that they suck at dealing with other people and treat others like stepping stones. That's a *zero* that can negate *all* of the big numbers preceding it. The rest doesn't matter.

And so we arrive at the "must be true" conclusion that understanding when you're in an additive system versus a multiplicative system, and which components need absolute reliability for the system to work, is a critical model to have in your head. Multiplicative thinking is a model related to the greater idea of systems thinking, another mental model well worth acquiring.

80. Commitment and Consistency Bias

We have an instinctual desire to remain consistent with our prior actions and beliefs. This can lead us to behave in irrational ways. Here's how the commitment and consistency fallacy can lead us to do things that aren't always in our best interest.

*"The difficulty lies not in the new ideas,
but in escaping the old ones, which ramify,
for those brought up as most of us have been,
into every corner of our minds."*

— John Maynard Keynes

Ben Franklin tells an interesting little story in his autobiography. Facing opposition to being reelected Clerk of the General Assembly, he sought to gain favor with the member so vocally opposing him:

Having heard that he had in his library a certain very scarce and curious book, I wrote a note to him, expressing my desire of perusing that book, and requesting he would do me the favour of lending it to me for a few days. He sent it immediately, and I return'd it in about a week with another note, expressing strongly my sense of the favour.

When we next met in the House, he spoke to me (which he had never done before), and with great civility; and he ever after manifested a readiness to serve me on all occasions, so that we became great friends, and our friendship continued to his death.

This is another instance of the truth of an old maxim I had learned, which says, "He that has once done you a kindness will be more ready to do you another, than he whom you yourself have obliged."

The man, having lent Franklin a rare and valuable book, sought to stay consistent with his past actions. He wouldn't, of course, lend a book to an unworthy man, would he?

Positive Self Image

Scottish philosopher and economist Adam Smith said in The Theory of Moral Sentiments: *The opinion which we entertain of our own character depends entirely on our judgments concerning our past conduct. It is so disagreeable to think ill of ourselves, that we often purposely turn away our view from those circumstances which might render that judgment unfavorable.*

Even when it acts against our best interest our tendency is to be consistent with our prior commitments, ideas, thoughts, words, and actions. As a byproduct of confirmation bias, we rarely seek disconfirming evidence of what we believe. This, after all, makes it easier to maintain our positive self-image.

Part of the reason this happens is our desire to appear and feel like we're right. We also want to show people our conviction. This shouldn't come as a surprise. Society values consistency and conviction even when it is *wrong*.

We associate consistency with intellectual and personal strength, rationality, honesty, and stability. On the other hand, the person who is perceived as inconsistent is also seen as confused, two-faced, even mentally ill in certain extreme circumstances.

A politician, for example, who wavers, gets labelled a flip flopper and can lose an election over it (John Kerry). A CEO who risks everything on a successful bet and holds a conviction that no one else holds is held to be a hero (Elon Musk).

But it's not just our words and actions that nudge our subconscious, but also how other people see us. There is a profound truth behind Eminem's lyrics: *I am, whatever you say I am. If I wasn't, then why would I say I am?*

If you think I'm talented, I *become* more talented in your eyes — in part because you labelling me as talented filters the way you see me. You start seeing more of my genius and less of my normal-ness, simply by way of staying consistent with your own words.

In his book Outliers, Malcolm Gladwell talks about how teachers simply identifying students as smart not only affected how the teachers saw their work but, more importantly, affected the opportunities teachers gave the students. Smarter students received better opportunities, which, we can reason, offers them better experiences. This in turn makes them better. It's almost a self-fulfilling prophecy.

And the more we invest in our beliefs of ourselves or others—think money, effort, or pain, the more sunk costs we have and the harder it becomes to change our mind. It doesn't matter if we're right. It doesn't matter if the Ikea bookshelf sucks, we're going to love it. In Too Much Invested to Quit, psychologist Allan Teger says something similar of the Vietnam War: “

The longer the war continued, the more difficult it was to justify the additional investments in terms of the value of possible victory. On the other hand, the longer the war continued, the more difficult it became to write off the tremendous losses without having anything to show for them.

As a consequence, there are few rules we abide by more than the “Don't make any promises that you can't keep.” This, generally speaking, is a great rule that keeps society together by ensuring that our commitments for the most part are real and reliable.

Aside from the benefits of preserving our public image, being consistent is simply easier and leads to a more predictable and consistent life. By being consistent in our habits and with previous decisions, we significantly reduce the need to think and can go on “auto-pilot” for most of our lives.

However beneficial these biases are, they too deserve deeper understanding and caution. Sometimes our drive to appear consistent can lure us into choices we otherwise would consider against our best interests. This is the essence of a harmful bias as opposed to a benign one: *We are hurting ourselves and others by committing it.*

A Slippery Slope

Part of why commitment can be so dangerous is because it is like a slippery slope – you only need a single slip to slide down completely. Therefore compliance to even tiny requests, which initially appear insignificant, have a good probability of leading to full commitment later.

People whose job it is to persuade us know this.

Among the more blunt techniques on the spectrum are those reported by a used-car sales manager in Robert Cialdini's book Influence. The dealer knows the power of commitment and that if we comply a little now, we are likely to comply fully later on. His advice to other sellers goes as follows:

“Put 'em on paper. Get the customer's OK on paper. Get the money up front. Control 'em. Control the deal. Ask 'em if they would buy the car right now if the price is right. Pin 'em down.”

This technique will be obvious to most of us. However, there are also more subtle ways to make us comply without us noticing.

A great example of a subtle compliance practitioner is Jo-ellen Demetrius, the woman currently reputed to be the best consultant in the business of jury selection.

Whenever screening potential jurors before a trial she asks an artful question:

“If you were the only person who believed in my client's innocence, could you withstand the pressure of the rest of the jury to change your mind?”

It's unlikely that any self-respecting prospective juror would answer negatively. And, now that the juror has made the implicit promise, it is unlikely that once selected he will give in to the pressure exerted by the rest of the jury.

Innocent questions and requests like this can be a great springboard for initiating a cycle of compliance.

The Lenient Policy

A great case study for compliance is the tactics that Chinese soldiers employed on American war captives during the Korean War. The Chinese were particularly effective in getting Americans to inform on one another. In fact, nearly all American prisoners in the Chinese camps are said to have collaborated with the enemy in one way or another. This was striking, since such behavior was rarely observed among American war prisoners during WWII. It raises the question of what secret trades led to the success of the Chinese?

Unlike the North Koreans, the Chinese did not treat the victims harshly. Instead they engaged in what they called “lenient policy” towards the captives, which was, in reality, a clever series of psychological assaults.

In their exploits the Chinese relied heavily on commitment and consistency tactics to receive the compliance they desired. At first, the Americans were not too collaborative, as they had been trained to provide only name, rank, and serial number, but the Chinese were patient.

They started with seemingly small but frequent requests to repeat statements like “The United States is not perfect” and “In a Communist country, unemployment is not a problem.” Once these requests had been complied with, the heaviness of the requests grew. Someone who had just agreed that United States was not perfect would be encouraged to expand on his thoughts about specific imperfections. Later he might be asked to write up and read out a list of these imperfections in a discussion group with other prisoners. “After all, it’s what you really believe, isn’t it?” The Chinese would then broadcast the essay readings not only to the whole camp, but to other camps and even the American forces in South Korea. Suddenly the soldier would find himself a “collaborator” of the enemy.

The awareness that the essays did not contradict his beliefs could even change his self-image to be consistent with the new “collaborator” label, often resulting in more cooperation with the enemy.

It is not surprising that very few American soldiers were able to avoid such “collaboration” altogether.

Foot in the Door

The small request growing into bigger requests as applied by the Chinese on American soldiers is also called the Foot-in-the-door Technique. It was first discovered by two scientists – Freedman and Fraser, who had worked on an experiment in which a fake volunteer worker asked home owners to allow a public-service billboard to be installed on their front lawns.

To get a better idea of how it would look, the home owners were even shown a photograph depicting an attractive house that was almost completely obscured by an ugly sign reading DRIVE CAREFULLY. While the request was quite understandably denied by 83 percent of residents, one particular group reacted favorably.

Two weeks earlier a different “volunteer worker” had come and asked the respondents of this group a similar request to display a much smaller sign that read BE A SAFE DRIVER. The request was so negligible that nearly all of them complied. However, the future effects of that request turned out to be so enormous that 76 percent of *this* group complied with the bigger, much less reasonable request (the big ugly sign).

At first, even the researchers themselves were baffled by the results and repeated the experiment on similar setups. The effect persisted. Finally, they proposed that the subjects must have distorted their own views about themselves as a result of their initial actions:

What may occur is a change in the person’s feelings about getting involved or taking action. Once he has agreed to a request, his attitude may change, he may become, in his own eyes, the kind of person who does this sort of thing, who agrees to requests made by strangers, who takes action on things he believes in, who cooperates with good causes.

The rule goes that once someone has instilled our self-image where they want it to be, we will comply naturally with the set of requests that adhere to the new self-view. Therefore we must be very careful about agreeing to even the smallest requests. Not only can it make us comply with larger requests later on, but it can make us even more willing to do favors that are only remotely connected to the earlier ones.

Even Cialdini, someone who knows this bias inside-out, admits to his fear that his behavior will be affected by consistency bias:

It scares me enough that I am rarely willing to sign a petition anymore, even for a position I support. Such an action has the potential to influence not only my future behavior but also my self-image in ways I may not want.

Further, once a person's self-image is altered, all sorts of subtle advantages become available to someone who wants to exploit that new image.

Give it, take it away later

Have you ever witnessed a deal that is a little too good to be true only to later be disappointed? You had already made up your mind, had gotten excited and were ready to pay or sign until a calculation error was discovered. Now with the adjusted price, the offer did not look all that great.

It is likely that the error was not an accident – this technique, also called low-balling, is often used by compliance professionals in sales. Cialdini, having observed the phenomenon among car dealers, tested its effects on his own students.

In an experiment with colleagues, he made two groups of students show up at 7:00 AM in the morning to do a study on “thinking processes”. When they called one group of students they immediately told them that the study starts at 7:00 AM. Unsurprisingly, only 24 percent wanted to participate.

However, for the other group of students, researchers threw a low-ball. The first question was whether they wanted to take part in a study of thinking processes. Fifty-six percent of them replied positively. Now, to those that agreed, the meeting time of 7:00 AM was revealed.

These students were given the opportunity to opt out, but none of them did. In fact, driven by their commitment, 95 percent of the low-balled students showed up to the Psychology Building at 7:00 AM as they had promised.

Do you recognize the similarities between the experiment and the sales situation?

The script of low-balling tends to be the same:

First, an advantage is offered that induces a favorable decision in the manipulator's direction. Then, *after* the decision has been made, but *before* the bargain is sealed, the original advantage is deftly removed (i.e., the price is raised, the time is changed, etc.). It would seem surprising that anyone would buy under these circumstances, yet many do. Often the self-created justifications provide so many new reasons for the decision that even when the dealer pulls away the original favorable rationale, like a low price, the decision is not changed. We stick with our old decision *even in the face of new information!*

Of course not *everyone* complies, but that's not the point. The effect is strong enough to hold for a good number of buyers, students or anyone else whose rate of compliance we may want to raise.

The Way Out

The first real defense to consistency bias is awareness about the phenomenon and the harm a certain rigidity in our decisions can cause us.

Robert Cialdini suggests two approaches to recognizing when consistency biases are unduly creeping into our decision making. The first one is to listen to our stomachs.

Stomach signs display themselves when we realize that the request being pushed is something we don't want to do.

He recalls a time when a beautiful young woman tried to sell him a membership he most certainly did not need by using the tactics displayed above. He writes:

I remember quite well feeling my stomach tighten as I stammered my agreement. It was a clear call to my brain, "Hey, you're being taken here!" But I couldn't see a way out. I had been cornered by my own words. To decline her offer at that point would have meant facing a pair of distasteful alternatives: If I tried to back out by protesting that I was not actually the man-about-town I had claimed to be during the interview, I would come off a liar; trying to refuse without that protest would make me come off a fool for not wanting to save \$1,200. I bought the entertainment package, even though I knew I had been set up. The need to be consistent with what I had already said snared me.

But then eventually he came up with the perfect counter-attack for later episodes, which allowed him to get out of the situation gracefully.

Whenever my stomach tells me I would be a sucker to comply with a request merely because doing so would be consistent with some prior commitment I was tricked into, I relay that message to the requester. I don't try to deny the importance of consistency; I just point out the absurdity of foolish consistency. Whether, in response, the requester shrinks away guiltily or retreats in bewilderment, I am content. I have won; an exploiter has lost.

The second approach concerns the signs that are felt within our heart and is best used when it is not really clear whether the initial commitment was wrongheaded.

Imagine you have recognized that your initial assumptions about a particular deal were not correct. The car is not extraordinarily cheap and the experiment is not as fun if you have to wake up at 6 AM to make it. Here it helps to ask one simple question:

"Knowing what I know, if I could go back in time, would I make the same commitment?"

Ask it frequently enough and the answer might surprise you.

81. Mental Model: Bias from Conjunction Fallacy

The bias from conjunction fallacy is a common reasoning error in which we believe that two events happening in conjunction is more probable than one of those events happening alone. Here's why this happens and how we can overcome the fallacy.

Daniel Kahneman and Amos Tversky spent decades in psychology research to disentangle patterns in errors of human reasoning. The duo discovered a variety of logical fallacies that we tend to make when facing information that appears vaguely familiar. These fallacies lead to bias — irrational behavior based on beliefs that are not always grounded in reality.

In his book *Thinking Fast and Slow*, which summarizes his and Tversky's life work, Kahneman introduces biases that stem from the conjunction fallacy – the false belief that a conjunction of two events is more probable than one of the events on its own.

What is Probability?

Probability can be a difficult concept. Most of us have an intuitive understanding of what probability is, but there is little consensus on what it actually means. It is just as vague and subjective a concept as *democracy*, *beauty* or *freedom*. However, this is not always troublesome – we can still easily discuss the notion with others. Kahneman reflects:

In all the years I spent asking questions about the probability of events, no one ever raised a hand to ask me, "Sir, what do you mean by probability?" as they would have done if I had asked them to assess a strange concept such as globability.

Everyone acted as if they knew how to answer my questions, although we all understood that it would be unfair to ask them for an explanation of what the word means.

While logicians and statisticians might disagree, to most of us probability is simply a tool that describes our degree of belief. For instance, we know that the sun will rise tomorrow and we consider it near impossible that there will be two suns up in the sky instead of one. In addition to the extremes, there are also events which lie somewhere in the middle of the probability spectrum, such as the degree of belief that it will rain tomorrow.

Despite its vagueness, probability has its virtues. Assigning probabilities helps us make the degree of belief actionable and also communicable to others. If we believe that the probability it will rain tomorrow is 90%, we are likely to carry an umbrella and suggest our family do so as well.

Probability, Base Rates, and Representativeness

Most of us are already familiar with representativeness and base rates. Consider the classic example of x number of black and y number of white-colored marbles in a jar. It is a simple exercise to tell what the probabilities of drawing each color are if you know their base rates (proportion). Using base rates is the obvious approach for estimations when no other information is provided.

However, Kahneman managed to prove that we have a tendency to ignore base rates in light of specific descriptions. He calls this phenomenon the Representativeness Bias. To illustrate representativeness bias, consider the example of seeing a person reading *The New York Times* on the New York subway. Which do you think would be a better bet about the reading stranger?

1) *She has a PhD.*

2) *She does not have a college degree.*

Representativeness would tell you to bet on the PhD, but this is not necessarily a good idea. You should seriously consider the second alternative because many more non-graduates than PhDs ride in New York subways. While a more significant proportion of PhDs may read *The New York Times*, the total number of *New York Times* readers with only high school degrees is likely to be much larger, even if the proportion itself is very slim.

In a series of similar experiments, Kahneman's subjects failed to recognize the base rates in light of individual information. This is unsurprising. Kahneman explains:

On most occasions, people who act friendly are in fact friendly. A professional athlete who is very tall and thin is much more likely to play basketball than football. People with a PhD are more likely to subscribe to The New York Times than people who ended their education after high school. Young men are more likely than elderly women to drive aggressively.

While following representativeness bias might improve your overall accuracy, it will not always be the statistically optimal approach.

In his bestseller *Moneyball*, Michael Lewis tells a story of Oakland A's baseball team coach, Billy Beane, who recognized this fallacy and used it to his advantage.

When recruiting new players for the team, instead of relying on scouts he relied heavily on statistics of past performance. This approach allowed him to build a team of great players that were passed up by other teams because they did not look the part. Needless to say, the team achieved excellent results at a low cost.

Conjunction Fallacy

While representativeness bias occurs when we fail to account for low base rates, conjunction fallacy occurs when we assign a higher probability to an event of higher specificity. This violates the laws of probability.

Consider the following study:

Participants were asked to rank four possible outcomes of the next Wimbledon tournament from most to least probable. Björn Borg was the dominant tennis player of the day when the study was conducted. These were the outcomes:

- A. Borg will win the match.*
- B. Borg will lose the first set.*
- C. Borg will lose the first set but win the match.*
- D. Borg will win the first set but lose the match.*

How would you order them?

Kahneman was surprised to see that most subjects ordered the chances by directly contradicting the laws of logic and probability. He explains:

The critical items are B and C. B is the more inclusive event and its probability must be higher than that of an event it includes. Contrary to logic, but not to representativeness or plausibility, 72% assigned B a lower probability than C.

If you thought about the problem carefully, you drew the following diagram in your head.

Losing the first set will always, by definition, be a more probable event than losing the first set and winning the match.

The Linda Problem

As discussed in [our piece on the Narrative Fallacy](#), the best-known and most controversial of Kahneman and Tversky's experiments involved a fictitious lady called Linda. The fictional character was created to illustrate the role heuristics play in our judgment and how it can be incompatible with logic. This is how they described Linda.

Linda is thirty-one years old, single, outspoken, and very bright. She majored in philosophy. As a student, she was deeply concerned with issues of discrimination and social justice, and also participated in antinuclear demonstrations.

Kahneman conducted a series of experiments, in which he showed that representativeness tends to cloud our judgments and that we ignore the base rates in light of stories. The Linda problem started off with the task to estimate the plausibility of 9 different scenarios that subjects were supposed to rank in order of likelihood.

Linda is a teacher in elementary school.

Linda works in a bookstore and takes yoga classes.

Linda is active in the feminist movement.

Linda is a psychiatric social worker.

Linda is a member of the League of Women Voters.

Linda is a bank teller.

Linda is an insurance salesperson.

Linda is a bank teller and is active in the feminist movement.

Kahneman was startled to see that his subjects judged the likelihood of Linda being a bank teller and a feminist more likely than her being just a bank teller. As explained earlier, doing so makes little sense. He went on to explore the phenomenon further:

In what we later described as "increasingly desperate" attempts to eliminate the error, we introduced large groups of people to Linda and asked them this simple question:

Which alternative is more probable?

Linda is a bank teller.

Linda is a bank teller and is active in the feminist movement.

This stark version of the problem made Linda famous in some circles, and it earned us years of controversy. About 85% to 90% of undergraduates at several major universities chose the second option, contrary to logic.

What is especially interesting about these results is that, even when aware of the biases in place, we do not discard them.

When I asked my large undergraduate class in some indignation, “Do you realize that you have violated an elementary logical rule?” someone in the back row shouted, “So what?” and a graduate student who made the same error explained herself by saying, “I thought you just asked for my opinion.”

The issue is not constrained to students and but also affects professionals.

The naturalist Stephen Jay Gould described his own struggle with the Linda problem. He knew the correct answer, of course, and yet, he wrote, “a little homunculus in my head continues to jump up and down, shouting at me—‘but she can’t just be a bank teller; read the description.’”

Our brains simply seem to prefer consistency over logic.

The Role of Plausibility

Representativeness and conjunction fallacy occurs because we make the mental shortcut from our perceived plausibility of a scenario to its probability.

The most coherent stories are not necessarily the most probable, but they are plausible, and the notions of coherence, plausibility, and probability are easily confused by the unwary. Representativeness belongs to a cluster of closely related assessments that are likely to be generated together. The most representative outcomes combine with the personality description to produce the most coherent stories.

Kahneman warns us about the effects of these biases on our perception of expert opinion and forecasting. He explains that we are more likely to believe scenarios that are illustrative rather than probable.

The uncritical substitution of plausibility for probability has pernicious effects on judgments when scenarios are used as tools of forecasting. Consider these two scenarios, which were presented to different groups, with a request to evaluate their probability:

A massive flood somewhere in North America next year, in which more than 1,000 people drown

An earthquake in California sometime next year, causing a flood in which more than 1,000 people drown

The California earthquake scenario is more plausible than the North America scenario, although its probability is certainly smaller. As expected, probability judgments were higher for the richer and more detailed scenario, contrary to logic. This is a trap for forecasters and their clients: adding detail to scenarios makes them more persuasive, but less likely to come true.

In order to appreciate the role of plausibility, he suggests we have a look at an example without an accompanying explanation.

Which alternative is more probable?

Jane is a teacher.

Jane is a teacher and walks to work.

In this case, when evaluating plausibility and coherence, there are no quick answers to the probability question, and we can easily conclude that the first one is more likely. The rule goes that in the absence of a competing intuition, logic prevails.

Taming our intuition

The first lesson to thinking clearly is to question how you think. We should not simply believe whatever comes to our mind – our beliefs must be constrained by logic. You don’t have to become an expert in probability to tame your intuition, but having a grasp of simple concepts will help. There are two main rules that are worth repeating in light of representativeness bias:

1) All probabilities add up to 100%.

This means that if you believe that there's a 90% chance it will rain tomorrow, there's a 10% chance that it will not rain tomorrow.

However, since you believe that there is only a 90% chance that it will rain tomorrow, you cannot be 95% certain that it will rain tomorrow morning.

We typically make this type of error, when we mean to say that, if it rains, there's a 95% probability it will happen in the morning. That's a different claim and the probability of raining tomorrow morning under such premises is $0.9 \times 0.95 = 85.5\%$.

This also means the odds that, if it rains, it will not rain in the morning, are $90.0\% - 85.5\% = 4.5\%$.

2) The second principle is called the Bayes rule.

It allows us to correctly adjust our beliefs with the diagnosticity of the evidence. Bayes rule follows the formula:

$$P(A|B) \propto P(A)P(B|A)$$

In essence, the formula states that the posterior odds are proportional to prior odds times the likelihood. Kahneman crystallizes two keys to disciplined Bayesian reasoning:

- Anchor your judgment of the probability of an outcome on a plausible base rate.
- Question the diagnosticity of your evidence.

Kahneman explains it with an example:

If you believe that 3% of graduate students are enrolled in computer science (the base rate), and you also believe that the description of Tom is 4 times more likely for a graduate student in computer science than in other fields, then Bayes's rule says you must believe that the probability that Tom is a computer science student is now 11%.

Four times as likely means that we expect roughly 80% of all computer science students to resemble Tom. We use this proportion to obtain the adjusted odds. (The calculation goes as follows: $0.03 \times 0.8 / (0.03 \times 0.8 + ((1 - 0.03) \times (1 - 0.8))) = 11\%$)

The easiest way to become better at making decisions is by making sure you question your assumptions and follow strong evidence. When evidence is anecdotal, adjust minimally, and trust the base rates. Odds are, you will be pleasantly surprised.

82. Bias from Liking/Loving: Why We Comply With Those We Love

The decisions that we make are rarely impartial. Most of us already know that we prefer to take advice from people that we like. We also tend to more easily *agree* with opinions formed by people we like. The tendency to judge in favor of people and symbols we like is called the bias from liking or loving.

We are more likely to ignore faults and comply with wishes of our friends or lovers rather than random strangers. We favor people, products, and actions associated with our favorite celebrities. Sometimes we even distort facts to facilitate love. The influence that our friends, parents, lovers, and idols exert on us can be enormous.

In general, this is a good thing, a bias that adds on balance rather than subtracts. It helps us form successful relationships, it helps us fall in love (and stay in love), it helps us form attachments with others that give us great happiness.

But we do want to be aware of where this tendency leads us awry.

For example, some people and companies have learned to use this influence to their advantage.

In his bestseller on social psychology Influence, Robert Cialdini tells a story about the successful strategy of Tupperware, which at the time reported sales of over \$2.5 million a day.

As many of us know, the company for a long time sold its kitchenware at parties thrown by friends of the potential customers. At each party, there was a Tupperware representative taking orders, but the hostess, the friend of the invitees, received a commission.

These potential customers are not blind to the incentives and social pressures involved.

Some of them don't mind it, others do, but all admit a certain degree of helplessness in their situation. Cialdini recalls a conversation with one of the frustrated guests:

It's gotten to the point now where I hate to be invited to Tupperware parties. I've got all the containers I need; and if I wanted any more, I could buy another brand cheaper in the store. But when a friend calls up, I feel like I have to go. And when I get there, I feel like I have to buy something. What can I do? It's for one of my friends.

We are more likely to buy in a familiar, friendly setting and under the obligation of friendship rather than from an unfamiliar store or a catalog. We simply find it much harder to say "no" or disagree when it's a friend. The possibility of ruining the friendship, or seeing our image altered in the eyes of someone we like, is a powerful motivator to comply.

The Tupperware example is a true "*lollapalooza*" in favor of manipulating people into buying things. Besides the liking tendency, there are several other factors at play: commitment/consistency bias, a bias from stress, an influence from authority, a reciprocation effect, and some direct incentives and disincentives, at least!

(Lollapaloozas, something we'll talk more about in the future, are when several powerful forces combine to create a non-linear outcome. A good way to think of this conceptually for now is that $1+1=3$.)

The liking tendency is so strong that it stretches beyond close friendships. It turns out we are also more likely to act in favor of certain types of strangers.

Can you recall meeting someone with whom you hit it off instantly, where it almost seemed like you'd known them for years after a 20-minute conversation? Developing such an instant bond with a stranger may seem like a mythical process, but it rarely is. There are several tactics that can be used to make us like something, or someone, more than we otherwise would.

Appearance and the Halo Effect

We all like engaging in activities with beautiful people. This is part of an automatic bias that falls into a category called The Halo Effect.

The Halo Effect occurs when a specific, positive characteristic determines the way a person is viewed by others on other, *unrelated* traits. In the case of beauty, it's been shown that we automatically assign favorable yet unrelated traits such as talent, kindness, honesty, and intelligence, with those we find physically attractive.

For the most part, this attribution happens unnoticed. For example, attractive candidates received more than twice as many votes as unattractive candidates in the 1974 Canadian federal elections. Despite the ample evidence of predisposition towards handsome politicians, follow-up research demonstrated that nearly three-quarters of Canadians surveyed strongly denied the influence of physical appearance in their voting decisions. The power of the Halo Effect is that it's mostly happening beneath the level of consciousness.

Similar forces are at play when it comes to hiring decisions and pay. While employers deny that they are strongly influenced by looks, studies show otherwise.

In one study evaluating hiring decisions based on simulated interviews, the applicants' grooming played a greater role in the outcome than job qualifications. Partly, this has a rational basis. We might assume that someone who shows up without the proper "look" for the job may be deficient in other areas. If they couldn't shave and put a tie on, how are we to expect them to perform with customers? Partly, though, it's happening subconsciously. Even if we never consciously say to ourselves that "Better grooming = better employee", we tend to act that way in our hiring.

These effects go even beyond the hiring phase — attractive individuals in the US and Canada have been estimated to earn an average of 12-14 percent more than their unattractive coworkers. Whether this is due to liking bias or perhaps the increased self-confidence that comes from above-average looks is hard to say.

Appearance is not the only quality that may skew our perceptions in favor of someone. The next one on the list is similarity.

Similarity

We like people who resemble us. Whether it's appearance, opinions, lifestyle or background, we tend to favor people who on some dimension are most similar to ourselves.

A great example of similarity bias is the case of dress. Have you ever been at an event where you felt out of place because you were either overdressed or underdressed? The uneasy feelings are not caused only by your imagination. Numerous studies suggest that we are more likely to do favors, such as giving a dime or signing a petition, to someone who looks like us.

Similarity bias can extend to even such ambiguous traits as interests and background. Many salesmen are trained to look for similarities to produce a favorable and trustworthy image in the eyes of their potential customers.

In Influence: The Psychology of Persuasion, Robert Cialdini explains:

If there is camping gear in the trunk, the salespeople might mention, later on, how they love to get away from the city whenever they can; if there are golf balls on the back seat, they might remark that they hope the rain will hold off until they can play the eighteen holes they scheduled for later in the day; if they notice that the car was purchased out of state, they might ask where a customer is from and report—with surprise—that they (or their spouse) were born there, too.

These are just a few of many examples which can be surprisingly effective in producing a sweet feeling of familiarity. Multiple studies illustrate the same pattern. We decide to fill out surveys from people with similar names, buy insurance from agents of similar age and smoking habits, and even decide that those who share our political views deserve their medical treatment sooner than the rest.

There is just one takeaway: even if the similarities are terribly superficial, we still may end up liking the other person more than we should.

“And what will a man naturally come to like and love, apart from his parent, spouse and child? Well, he will like and love being liked and loved.”

— Charlie Munger

Praise and Compliments

We are all phenomenal suckers for flattery. These are not my words, but words of Robert Cialdini and they ring a bell. Perhaps, more than anything else in this world we love to be loved and, consequently, we love those that love us.

Consider the technique of Joe Girard, who has been continuously called the world’s “greatest car salesman” and has made it to the Guinness World Record book.

Each month Joe prints and sends over 13,000 holiday cards to his former customers.

While the theme of the card varies depending on the season and celebration, the printed message always remains the same. On each of those cards Girard prints three simple words “I like you” and his name. He explains:

“There’s nothing else on the card, nothin’ but my name. I’m just telling ’em that I like ’em.”

“I like you.” It came in the mail every year, 12 times a year, like clockwork.

Joe understood a simple fact about humans – we love to be loved.

As numerous experiments show, regardless of whether the praise is deserved or not, we cannot help but develop warm feelings to those that provide it. Our reaction can be so automatic, that we develop liking even when the attempt to win our favor is an obvious one, as in the case of Joe.

Familiarity

In addition to liking those that like us and look like us, we also tend to like those who we know. That’s why repeated exposure can be a powerful tool in establishing liking.

There is a fun experiment you can do to understand the power of familiarity.

Take a picture of yourself and create a mirror image in one of the editing tools. Now with the two pictures at hand decide which one – the real or the mirror image you like better.

Show the two pictures to a friend and ask her to choose the better one as well.

If you and your friend are like the group on whom this trick was tried, you should notice something odd. Your friend will prefer the true print, whereas you will think you look better in the mirror image. This is because you both prefer the faces you are used to. Your friend always sees you from her perspective, whereas you have learned to recognize and love your mirror image.

The effect, of course, extends beyond faces into places, names, and even ideas.

For example, in elections, we might prefer candidates whose names sound more familiar.

The Ohio Attorney-General post was claimed by a man who, shortly before his candidacy, changed his last name to Brown – a family name of Ohio political tradition. Apart from his surname, there was little to nothing that separated him from other equally if not more capable candidates.

How could such a thing happen? The answer lies partly in the unconscious way that familiarity affects our liking. Often we don’t realize that our attitude toward something has been influenced by the number of times we have been exposed to it in the past.

Loving by Association and Referral

Charisma or attraction are not prerequisites for liking — a mere association with someone you like or trust can be enough.

The bias from association shows itself in many other domains and is especially strong when we associate with the person we like the most — ourselves. For example, the relationship between a sports fan and his local team can be highly personal even though the association is often based only on shared location. For the fan, however, the team is an important part of his self-identity. If the team or athlete wins, he wins as well, which is why sports can be so emotional. The most dedicated fans are ready to get into fights, burn

cars or even kill to defend the honor of their team. Such associated sense of pride and achievement is as true for celebrities as it is for sports.

When Kevin Costner delivered his acceptance speech after winning the best picture award for *Dances With Wolves*, he said:

"While it may not be as important as the rest of the world situation, it will always be important to us. My family will never forget what happened here; my Native American brothers and sisters, especially the Lakota Sioux, will never forget, and the people I went to high school with will never forget."

The interesting part of his words is the notion that his high school peers will remember, which is probably true. His former classmates are likely to tell people that they went to school with Costner, even though they themselves had no connection with the success of the movie.

Costner's words illustrate that even a trivial association with success may reap benefits and breed confidence.

Who else do we like besides ourselves, celebrities and our sports teams?

People we've met through those who are close to us – our neighbors, friends, and family. It is common sense that a referral from someone we trust is enough to trigger mild liking and favorable initial opinions.

There are a number of companies that use friend referral as a sales tactic. Network providers, insurers, and other subscription services offer a number of benefits for those of us who give away our friends' contact details.

The success of this method rests on the implicit idea that turning down the sales rep who says "your friend Jenny/Allan suggested I call you" feels nearly as bad as turning down Jenny or Allan themselves. This tactic, when well executed, leads to a never-ending chain of new customers.

Can We Avoid Liking?

Perhaps the right question to ask here is not "how can we avoid the bias from liking", but *when should we?*

Someone who is conditioned to like the right people and pick their idols carefully can greatly benefit from these biases. In his famous talk, *The Psychology of Human Misjudgment*, Charlie Munger recalls that both he and Warren Buffett benefitted from liking admirable persons:

One common, beneficial example for us both was Warren's uncle, Fred Buffett, who cheerfully did the endless grocery-store work that Warren and I ended up admiring from a safe distance. Even now, after I have known so many other people, I doubt if it is possible to be a nicer man than Fred Buffett was, and he changed me for the better.

The keywords here are "from a safe distance".

If dealing with salesmen and others who clearly benefit from your liking, it might be a good idea to check whether you have been influenced. In these unclear cases, Cialdini advises us to focus on our *feelings* rather than the other person's *actions* that may produce liking. Ask yourself how much of what you feel is due to liking versus the actual facts of the situation.

The time to call out the defense is when we feel ourselves liking the practitioner more than we *should* under the circumstances when we feel manipulated.

Once we have recognized that we like the requester more than we would expect under the given circumstances, we should take a step back and question ourselves. Are you doing the deal because you like someone or is it because it is indeed the best option out there?

83. Bias from Disliking/Hating

(This is a follow-up to our post on the Bias from Liking/Loving, which you can [find here](#).)

Think of a cat snarling and spitting, lashing with its tail and standing with its back curved. Her pulse is elevated, blood vessels constricted and muscles tense. This reaction may sound familiar, because everyone has experienced the same tensed-up feeling of rage at least once in their lives.

When rage is directed towards an external object, it becomes hate. Just as we learn to love certain things or people, we learn to hate others.

There are several cognitive processes that awaken the hate within us and most of them stem from our need for self-protection.

Reciprocation

We tend to dislike people who dislike us (and, true to Newton, with equal strength.) The more we perceive they hate us, the more we hate them.

Competition

A lot of hate comes from scarcity and competition. Whenever we compete for resources, our own mistakes can mean good fortune for others. In these cases, we affirm our own standing and preserve our self-esteem by blaming others.

Robert Cialdini explains that because of the competitive environment in American classrooms, school desegregation may increase the tension between children of different races instead of decreasing it. Imagine being a secondary school child:

If you knew the right answer and the teacher called on someone else, you probably hoped that he or she would make a mistake so that you would have a chance to display your knowledge. If you were called on and failed, or if you didn't even raise your hand to compete, you probably envied and resented your classmates who knew the answer.

At first we are merely annoyed. But then as the situation fails to improve and our frustration grows, we are slowly drawn into false attributions and hate. We keep blaming and associating “the others” who are doing better with the loss and scarcity we are experiencing (or perceive we are experiencing). That is one way our emotional frustration boils into hate.

Us vs. Them

The ability to separate friends from enemies has been critical for our safety and survival. Because mistaking the two can be deadly, our mental processes have evolved to quickly spot potential threats and react accordingly. We are constantly feeding information about others into our “people information lexicon” that forms not only our view of individuals, whom we must decide how to act around, but entire classes of people, as we average out that information.

To shortcut our reactions, we classify narrowly and think in dichotomies: right or wrong, good or bad, heroes or villains. (The type of Grey Thinking we espouse is almost certainly *unnatural*, but, then again, so is a good golf swing.) Since most of us are merely average at everything we do, even superficial and small differences, such as race or religious affiliation, can become an important source of identification. We are, after all, creatures who seek to belong to groups above all else.

Seeing ourselves as part of a special, different and, in its own way, superior group, decreases our willingness to empathize with the other side. This works both ways – the hostility towards the others also increases the solidarity of the group. In extreme cases, we are so drawn towards the inside view that we create a strong picture of the enemy that has little to do with reality or our initial perceptions.

From Compassion to Hate

We think of ourselves as compassionate, empathetic and cooperative. *So why do we learn to hate?*

Part of the answer lies in the fact that we think of ourselves in a specific way. If we cannot reach a consensus, then the other side, which is in some way different from us, must necessarily be uncooperative for our assumptions about our own qualities to hold true. Our inability to examine the situation from all sides and shake our beliefs, together with self-justifying behavior, can lead us to conclude that others are the problem. Such asymmetric views, amplified by strong perceived differences, often fuel hate.

What started off as odd or difficult to understand, has quickly turned into unholy.

If the situation is characterized by competition, we may also see ourselves as a *victim*. The others, who abuse our rights, take away our privileges or restrict our freedom are seen as bullies who deserve to be punished. We convince ourselves that we are doing good by doing harm to those who threaten to cross the line.

This is understandable. In critical times our survival indeed may depend on our ability to quickly spot and neutralize dangers. The cost of a false positive – mistaking a friend for a foe – is much lower than the potentially *fatal* false negative of mistaking our adversaries for innocent allies. As a result, it is safest to assume that anything we are not familiar with is dangerous by default. Natural selection, by its nature, “keeps what works,” and this tendency towards distrust of the unfamiliar probably survived in that way.

The Displays of Hate

Physical and psychological pain is very mobilizing. We despise foods that make us nauseous and people that have hurt us. Because we are scared to suffer, we end up either avoiding or destroying the “enemy”, which is why revenge can be pursued with such vengeance. In short, hate is a defense against enduring pain repeatedly.

There are several ways that the bias for disliking and hating display themselves to the outer world. The most obvious of them is war, which seems to have been more or less prevalent throughout the history of mankind.

This would lead us to think that war may well be unavoidable. In his famous talk, *The Psychology of Human Misjudgment*, Charlie Munger offers the more moderate opinion that while hatred and dislike cannot be avoided, the instances of war can be minimized by channeling our hate and fear into less destructive behaviors. (A good political system allows for dissent and disagreement without explosions of blood upheaval.)

Even with the spread of religion, and the advent of advanced civilization, modern war remains pretty savage. But we also get what we observe in present-day Switzerland and the United States, wherein the clever political arrangements of man “channel” the hatreds and dislikings of individuals and groups into nonlethal patterns including elections.

But these dislikings and hatreds that are arguably inherent to our nature never go away completely and transcend themselves into politics. Think of the dichotomies. There is the left versus the right wing, the nationalists versus the communists and libertarians vs. authoritarians. This might be the reason why there are maxims like: *“Politics is the art of marshaling hatreds.”*

Finally, as we move away from politics, arguably the most sophisticated and civilized way of channeling hatred is litigation. Charlie Munger attributes the following words to Warren Buffett:

“A major difference between rich and poor people is that the rich people can spend their lives suing their relatives.”

While most of us reflect on our memories of growing up with our siblings with fondness, there are cases where the competition for shared attention or resources breeds hatred. If the siblings can afford it, they will sometimes litigate endlessly to lay claims over their parents’ property or attention.

Under the Influence of Bias

There are several ways that bias from hating can interfere with our normal judgement and lead to suboptimal decisions.

Ignoring Virtues of The Other Side

Michael Faraday was once asked after a lecture whether he implied that a hated academic rival was always wrong. His reply was short and firm "He's not that consistent." Faraday must have recognized the bias from hating and corrected for it with the witty comment. What we should recognize here is that no situation is ever black or white. We all have our virtues and we all have our weaknesses. However, when possessed by the strong emotions of hate, our perceptions can be distorted to the extent that we fail to recognize any good in the opponent at all. This is driven by consistency bias, which motivates us to form a coherent ("she is all-round bad") opinion of ourselves and others.

Association Fueled Hate

The principle of association goes that the nature of the news tends to infect the teller. This means that the worse the experience, the worse the impression of anything *related* to it. Association is why we blame the messenger who tells us something that we don't want to hear even when they didn't cause the bad news. (Of course, this creates an incentive not to speak the truth and avoid giving bad news.)

A classic example is an unfortunate and confused weatherman, who receives hate mail, whenever it rains. One went so far as to seek advice from the Arizona State professor of psychology, Robert Cialdini, whose work we have discussed before.

Cialdini explained to him that in light of the destinies of other messengers, he was born lucky. Rain might ruin someone's holiday plans, but it will rarely change the destiny of a nation, which was the case of Persian war messengers. Delivering good news meant a feast, whereas delivering bad news resulted in their death.

The weatherman left Cialdini's office with a sense of privilege and relief.

"Doc," he said on his way out, "I feel a lot better about my job now. I mean, I'm in Phoenix where the sun shines 300 days a year, right? Thank God I don't do the weather in Buffalo."

Fact Distortion

Under the influence of liking or disliking bias, we tend to fill gaps in our knowledge by building our conclusions on assumptions, which are based on very little evidence.

Imagine you meet a woman at a party and find her to be a self-centered, unpleasant conversation partner. Now her name comes up as someone who could be asked to contribute to a charity. How likely do you feel it is that she will give to the charity?

In reality, you have no useful knowledge, because there is little to nothing that should make you believe that people who are self-centered are not also generous contributors to charity. The two are unrelated, yet because of the well-known fundamental attribution error, we often assume one is correlated to the other.

By association, you are likely to believe that this woman is not likely to be generous towards charities despite lack of any evidence. And because now you also believe she is stingy and ungenerous, you probably dislike her even more.

This is just an innocent example, but the larger effects of such distortions can be so extreme that they lead to a major miscognition. Each side literally believes that every single bad attribute or crime is attributable to the opponent.

Charlie Munger explains this with a relatively recent example:

When the World Trade Center was destroyed, many Pakistanis immediately concluded that the Hindus did it, while many Muslims concluded that the Jews did it. Such factual distortions often make mediation between opponents locked in hatred either difficult or impossible. Mediations between Israelis and Palestinians are difficult because facts in one side's history overlap very little with facts from the other side's. These distortions and the overarching mistrust might be why some conflicts seem to never end.

Avoiding Being Hated

To varying degrees, we value acceptance and affirmation from others. Very few of us wake up wanting to be disliked or rejected. Social approval, at its heart the cause of social influence, shapes behavior and contributes to conformity. Francois VI, Duc de La

Rochefoucauld wrote: "We only confess our little faults to persuade people that we have no big ones."

Remember the old adage, "The nail that sticks out gets hammered down." This is why we don't openly speak the truth or question people, we don't want to be the nail.

How do we resolve hate?

It is only normal that we can find more common ground with some people than with others. But are we really destined to fall into the traps of hate or is there a way to take hold of these biases?

That's a question worth over a hundred million lives. There are ways that psychologists think that we can minimize prejudice against others.

Firstly, we can engage with others in sustained close contact to breed our familiarity. The contact must not only be prolonged, but also positive and cooperative in nature – either working towards a common cause or against a common enemy.

Secondly, we also reduce prejudice by attaining equal status in all aspects, including education, income and legal rights. This effect is further reinforced, when equality is supported not only "on paper", but also ingrained within broader social norms.

And finally the obvious – we should practice awareness of our own emotions and ability to hold back on the temptations to dismiss others. Whenever confronted with strong feelings it might simply be best to sit back, breathe and do our best to eliminate the distorted thinking.

84. What Are You Doing About It? Reaching Deep Fluency with Mental Models

The mental models approach is very intellectually appealing, almost seductive to a certain type of person. (It certainly is for us.)

The whole idea is to take the world's greatest, most useful ideas and make them work for you!

How hard can it be?

Nearly all of the models *themselves* are perfectly well understandable by the average well-educated knowledge worker, including all of you reading this piece. Ideas like Bayesian updating, multiplicative thinking, hindsight bias, or the bias from envy and jealousy, are all obviously true and part of the reality we live in.

There's a bit of a problem we're seeing though: People are reading the stuff, enjoying it, agreeing with it...but not taking action. It's not becoming part of their standard repertoire. Let's say you followed up on Bayesian thinking after reading our post on it — you spent some time soaking in Thomas Bayes' great wisdom on updating your understanding of the world incrementally and probabilistically rather than changing your mind in black-and-white. Great!

But a week later, what have you done with that knowledge? How has it actually impacted your life? If the honest answer is "It hasn't," then haven't you *really* wasted your time? Ironically, it's this habit of "going halfway" instead of "going all the way," like Sisyphus constantly getting halfway up the mountain, which is the *biggest waste of time*!

See, the common reason why people don't truly "follow through" with all of this stuff is that they haven't raised their knowledge to a "deep fluency" — they're skimming the surface. They pick up bits and pieces — some heuristics or biases here, a little physics or biology there, and then call it a day and pull up Netflix. They get a little understanding, but not that much, and certainly no *doing*.

The better approach, if you actually care about making changes, is to imitate Charlie Munger, Charles Darwin, and Richard Feynman, and start raising your knowledge of the Big Ideas to a deep fluency, and then figuring out systems, processes, and mental tricks to implement them in your own life.

Let's work through an example.

Say you're just starting to explore all the wonderful literature on heuristics and biases and come across the idea of Confirmation Bias: The idea that once we've landed on an idea we really like, we tend to keep looking for further data to *confirm* our already-held notions rather than trying to *disprove* our idea.

This is common, widespread, and perfectly natural. We all do it. John Kenneth Galbraith put it best:

"In the choice between changing one's mind and proving there's no need to do so, most people get busy on the proof."

Now, what most people do, the ones you're trying to outperform, is say "Great idea! Thanks Galbraith." and then stop thinking about it.

Don't do that!

The next step would be to push a bit further, to get beyond the sound bite: *What's the process that leads to confirmation bias? Why do I seek confirmatory information and in which contexts am I particularly susceptible? What other models are related to the confirmation bias? How do I solve the problem?*

The answers are out there: They're in Daniel Kahneman and in Charlie Munger and in Elster. They're available by searching through Farnam Street.

The big question: How far do you go? A good question without a perfect answer. But the best test I can think of is to perform something like the Feynman technique, and to think about the chauffeur problem.

Can you explain it simply to an intelligent layperson, using vivid examples? Can you answer all the follow-ups? That's fluency. And you must be careful not to fool yourself, because in the wise words of Feynman, "...*you are the easiest person to fool.*"

While that's great work, you're not done yet. You have to make the rubber hit the road now. Something has to *happen* in your life and mind.

The way to do that is to come up with rules, systems, parables, and processes of your own, or to copy someone else's that are obviously sound.

In the case of Confirmation Bias, we have two wonderful models to copy, one from each of the Charlies — Darwin, and Munger.

Darwin had rule, one we have written about before but will restate here: *Make a note, immediately, if you come across a thought or idea that is contrary to something you currently believe.*

As for Munger, he implemented a rule in his own life: "*I never allow myself to have an opinion on anything that I don't know the other side's argument better than they do.*"

Now we're getting somewhere! With the implementation of those two habits and some well-earned deep fluency, you can immediately, *tomorrow*, start improving the quality of your decision-making.

Sometimes when we get outside the heuristic/biases stuff, it's less obvious how to make the "rubber hit the road" — and that will be a constant challenge for you as you take this path.

But that's also the fun part! With every new idea and model you pick up, you also pick up the opportunity to synthesize for yourself a useful little parable to make it stick or a new habit that will help you *use it*. Over time, you'll come up with hundreds of them, and people might even look to you when they're having problems doing it themselves!

Look at Buffett and Munger — both guys are absolute machines, chock full of pithy little rules and stories they use in order to *implement and recall* what they've learned.

For example, Buffett discovered early on the manipulative psychology behind open-outcry auctions. What did he do? *He made a rule to never go to one! That's how it's done.*

Even if you can't come up with a great rule like that, you *can* figure out a way to use any new model or idea you learn. It just takes some creative thinking.

Sometimes it's just a little mental rule or story that *sticks* particularly well. (Recall one of the prime lessons from our series on memory: Salient, often used, well-associated, and important information sticks best.)

We did this very thing recently with Lee Kuan Yew's Rule. What a *trite* way to refer to the simple idea of asking if something actually works...attributing it to a Singaporean political leader!

But that's exactly the point. Give the thing a name and a life and, like clockwork, you'll start recalling it. The phrase "*Lee Kuan Yew's Rule*" actually appears in my head when I'm approaching some new system or ideology, and as soon as it does, I find myself backing away from ideology and towards pragmatism. Exactly as I'd hoped.

Your goal should be to create about a thousand of those little tools in your head, attached to a deep fluency in the material from which it came.

I can hear the objection coming. Who has time for this stuff?

You do. It's about making time for the things that really matter. *And what could possibly matter more than upgrading your whole mental operating system?* I solemnly promise that you're spending way more time right now making sub-optimal decisions and trying to deal with the fallout.

If you need help learning to manage your time right this second, check out the resources in our [learning community](#) including our productivity seminar, which changed thousands people's lives for the better. The central idea is to become more thoughtful and deliberate with how you spend your hours. When you start doing that, you'll notice you *do* have an hour a day to spend on this Big Ideas stuff.

Once you find that solid hour (or more), start using it in the way outlined above, and let the world's great knowledge *actually* start making an impact. Just do a little every day.

What you'll notice, over the weeks and months and years of doing this, is that your mind will *really change!* It has to! And with that, your life will change too. The only way to fail at improving your brain is by imitating Sisyphus, pushing the boulder halfway up, over and over.

Unless and until you really understand this, you'll continue spinning your wheels. So here's your call to action. Go get to it!

85. The Need for Biological Thinking to Solve Complex Problems

“Biological thinking and physics thinking are distinct, and often complementary, approaches to the world, and ones that are appropriate for different kinds of systems.”

How should we think about complexity? Should we use a biological or physics system? The answer, of course, is that it depends. It's important to have both tools available at your disposal.

These are the questions that Samuel Arbesman explores in his fascinating book Overcomplicated: Technology at the Limits of Comprehension.

[B]iological systems are generally more complicated than those in physics. In physics, the components are often identical—think of a system of nothing but gas particles, for example, or a single monolithic material, like a diamond. Beyond that, the types of interactions can often be uniform throughout an entire system, such as satellites orbiting a planet.

Biology is different, and there is something meaningful to be learned from a biological approach to thinking.

In biology, there are a huge number of types of components, such as the diversity of proteins in a cell or the distinct types of tissues within a single creature; when studying, say, the mating behavior of blue whales, marine biologists may have to consider everything from their DNA to the temperature of the oceans. Not only is each component in a biological system distinctive, but it is also a lot harder to disentangle from the whole. For example, you can look at the nucleus of an amoeba and try to understand it on its own, but you generally need the rest of the organism to have a sense of how the nucleus fits into the operation of the amoeba, how it provides the core genetic information involved in the many functions of the entire cell.

Arbesman makes an interesting point here when it comes to how we should look at technology. As the interconnections and complexity of technology increases, it increasingly resembles a biological system rather than a physics one. There is another difference.

[B]iological systems are distinct from many physical systems in that they have a history. Living things evolve over time. While the objects of physics clearly do not emerge from thin air—astrophysicists even talk about the evolution of stars—biological systems are especially subject to evolutionary pressures; in fact, that is one of their defining features. The complicated structures of biology have the forms they do because of these complex historical paths, ones that have been affected by numerous factors over huge amounts of time. And often, because of the complex forms of living things, where any small change can create unexpected effects, the changes that have happened over time have been through tinkering: modifying a system in small ways to adapt to a new environment.

Biological systems are generally hacks that evolved to be good enough for a certain environment. They are far from pretty top-down designed systems. And to accommodate an ever-changing environment, they are rarely the most optimal system on a micro-level, preferring to optimize for survival over any one particular attribute. And it's not the survival of the individual that's optimized, it's the survival of the species.

Technologies can appear robust until they are confronted with some minor disturbance, causing a catastrophe. The same thing can happen to living things. For example, humans can adapt incredibly well to a large array of environments, but a tiny change in a person's genome can cause dwarfism, and two copies of that mutation invariably cause death. We are of a different scale and material from a particle accelerator or a computer network, and yet these systems have profound similarities in their complexity and fragility.

Biological thinking, with a focus on details and diversity, is a necessary tool to deal with complexity.

The way biologists, particularly field biologists, study the massively complex diversity of organisms, taking into account their evolutionary trajectories, is therefore particularly appropriate for understanding our technologies. Field biologists often act as naturalists—collecting, recording, and cataloging what they find around them—but even more than that, when confronted with an enormously complex ecosystem, they don't immediately try to understand it all in its totality. Instead, they recognize that they can study only a tiny part of such a system at a time, even if imperfectly. They'll look at the interactions of a handful of species, for example, rather than examine the complete web of species within a single region. Field biologists are supremely aware of the assumptions they are making, and know they are looking at only a sliver of the complexity around them at any one moment. [...]

When we're dealing with different interacting levels of a system, seemingly minor details can rise to the top and become important to the system as a whole. We need "Field biologists" to catalog and study details and portions of our complex systems, including their failures and bugs. This kind of biological thinking not only leads to new insights, but might also be the primary way forward in a world of increasingly interconnected and incomprehensible technologies.

Waiting and observing isn't enough.

Biologists will often be proactive, and inject the unexpected into a system to see how it reacts. For example, when biologists are trying to grow a specific type of bacteria, such as a variant that might produce a particular chemical, they will resort to a process known as mutagenesis. Mutagenesis is what it sounds like: actively trying to generate mutations, for example by irradiating the organisms or exposing them to toxic chemicals.

When systems are too complex for human understanding, often we need to insert randomness to discover the tolerances and limits of the system. One plus one doesn't always equal two when you're dealing with non-linear systems. For biologists, tinkering is the way to go.

As Stewart Brand noted about legacy systems, "Teasing a new function out of a legacy system is not done by command but by conducting a series of cautious experiments that with luck might converge toward the desired outcome."

When Physics and Biology Meet

This doesn't mean we should abandon the physics approach, searching for underlying regularities in complexity. The two systems complement one another rather than compete. Arbesman recommends asking the following questions:

When attempting to understand a complex system, we must determine the proper resolution, or level of detail, at which to look at it. How fine-grained a level of detail are we focusing on? Do we focus on the individual enzyme molecules in a cell of a large organism, or do we focus on the organs and blood vessels? Do we focus on the binary signals winding their way through circuitry, or do we examine the overall shape and function of a computer program? At a larger scale, do we look at the general properties of a computer network, and ignore the individual machines and decisions that make up this structure?

When we need to abstract away a lot of the details and lean on physics thinking more.

Think about it from an organizational perspective. The new employee at the lowest level is focused on the specific details of their job, whereas the executive is focused on systems, strategy, culture, and flow — how things interact and reinforce one another. The details of the new employee's job are lost on them.

We can't use one system, whether biological or physics, exclusively. That's fragile thinking. Instead, we need to combine both systems.

In Cryptonomicon, a novel by Neal Stephenson, he makes exactly this point talking about the structure of the pantheon of Greek gods:

And yet there is something about the motley asymmetry of this pantheon that makes it more credible. Like the Periodic Table of the Elements or the family tree of the elementary particles, or just about any anatomical structure that you might pull up out of a cadaver, it has enough of a pattern to give our minds something to work on and yet an irregularity that indicates some kind of organic provenance—you have a sun god and a moon goddess, for example, which is all clean and symmetrical, and yet over here is Hera, who has no role whatsoever except to be a literal bitch goddess, and then there is Dionysus who isn't even fully a god—he's half human—but gets to be in the Pantheon anyway and sit on Olympus with the Gods, as if you went to the Supreme Court and found Bozo the Clown planted among the justices.

86. Peter Bevelin on Seeking Wisdom, Mental Models, Learning, and a Lot More

One of the most impactful books we've ever come across is the wonderful Seeking Wisdom: From Darwin to Munger, written by the Swedish investor Peter Bevelin. In the spirit of multidisciplinary learning, *Seeking Wisdom* is a compendium of ideas from biology, psychology, statistics, physics, economics, and human behavior.

Mr. Bevelin is out with a new book full of wisdom from Warren Buffett & Charlie Munger: All I Want to Know is Where I'm Going to Die So I Never Go There. We were fortunate enough to have a chance to interview Peter recently, and the result is the wonderful discussion below.

What was the original impetus for writing these books?

The short answer: To improve my thinking. And when I started writing on what later became Seeking Wisdom I can express it even simpler: *"I was dumb and wanted to be less dumb."* As Munger says: *"It's ignorance removal...It's dishonorable to stay stupider than you have to be."* And I had done some stupid things and I had seen a lot of stupidity being done by people in life and in business.

A seed was first planted when I read Charlie Munger's talk, A Lesson on Worldly Wisdom, and another one where he referred to Darwin as a great thinker. So I said to myself: I am 42 now. Why not take some time off business and spend a year learning, reflecting and write about the subject Munger introduced to me – human behavior and judgments.

None of my writings started out as a book project. I wrote my first book – *Seeking Wisdom* – as a memorandum for myself with the expectation that I could transfer some of its essentials to my children. I learn and write because I want to be a little wiser day by day. I don't want to be a great-problem-solver. I want to avoid problems – prevent them from happening and doing right from the beginning. And I focus on consequential decisions. To paraphrase Buffett and Munger – decision-making is not about making brilliant decisions, but avoiding terrible ones. Mistakes and dumb decisions are a fact of life and I'm going to make more, but as long as I can avoid the big or "fatal" ones I'm fine.

So I started to read and write to learn what works and not and why. And I liked Munger's *"All I want to know is where I'm going to die so I'll never go there"* approach. And as he said, *"You understand it better if you go at it the way we do, which is to identify the main stupidities that do bright people in and then organize your patterns for thinking and developments, so you don't stumble into those stupidities."* Then I "only" had to a) understand the central "concept" and its derivatives and describe it in as simple way as possible for me and b) organize what I learnt in a way that was logical and useful for me. And what better way was there to learn this from those who already knew this?

After I learnt some things about our brain, I understood that thinking doesn't come naturally to us humans – most is just unconscious automatic reactions. Therefore I needed to set up the environment and design a system that helped me make it easier to know what to do and prevent and avoid harm. Things like simple rules of thumbs, tricks and filters. Of course, I could only do that if I first had the foundation. And as the years have passed, I've found that filters are a great way to save time and misery. As Buffett says, "I process information very quickly since I have filters in my mind." And they have to be simple – as the proverb says, "Beware of the door that has too many keys." The more complicated a process is, the less effective it is.

Why do I write? Because it helps me understand and learn better. And if I can't write something down clearly, then I have not really understood it. As Buffett says, *"I learn while I think when I write it out. Some of the things, I think I think, I find don't make any sense when I start trying to write them down and explain them to people ... And if it can't stand applying pencil to paper, you'd better think it through some more."*

My own test is one that a physicist friend of mine told me many years ago, 'You haven't really understood an idea if you can't in a simple way describe it to almost anyone.' Luckily, I don't have to understand zillion of things to function well.

And even if some of mine and others thoughts ended up as books, they are all living documents and new starting points for further, learning, un-learning and simplifying/clarifying. To quote Feynman, *"A great deal of formulation work is done in writing the paper, organizational work, organization. I think of a better way, a better way, a better way of getting there, of proving it. I never do much — I mean, it's just cleaner, cleaner and cleaner. It's like polishing a rough-cut vase. The shape, you know what you want and you know what it is. It's just polishing it. Get it shined, get it clean, and everything else."*

Which book did you learn the most from the experience of writing/collecting?

Seeking Wisdom because I had to do a lot of research – reading, talking to people etc. Especially in the field of biology and brain science since I wanted to first understand what influences our behavior. I also spent some time at a Neurosciences Institute to get a better understanding of how our anatomy, physiology and biochemistry constrained our behavior. And I had to work it out my own way and write it down in my own words so I really could understand it. It took a lot of time but it was a lot of fun to figure it out and I learnt much more and it stuck better than if I just had tried to memorize what somebody else had already written. I may not have gotten everything letter perfect but good enough to be useful for me.

As I said, the expectation wasn't to create a book. In fact, that would have removed a lot of my motivation. I did it because I had an interest in becoming better. It goes back to the importance of intrinsic motivation. As I wrote in Seeking Wisdom: *"If we reward people for doing what they like to do anyway, we sometimes turn what they enjoy doing into work. The reward changes their perception. Instead of doing something because they enjoy doing it, they now do it because they are being paid. The key is what a reward implies. A reward for our achievements makes us feel that we are good at something thereby increasing our motivation. But a reward that feels controlling and makes us feel that we are only doing it because we're paid to do it, decreases the appeal."*

It may sound like a cliché but the joy was in the journey – reading, learning and writing – not the destination – the finished book. Has the book made a difference for some people? Yes, I hope so but often people revert to their old behavior. Some of them are the same people who – to paraphrase something that is attributed to Churchill – occasionally should check their intentions and strategies against their results. But reality is what Munger once said, *"Everyone's experience is that you teach only what a reader almost knows, and that seldom."* But I am happy that my books had an impact and made a difference to a few people. That's enough.

Why did the new book (All I Want To Know Is Where I'm Going To Die So I'll Never Go There) have a vastly different format?

It was more fun to write about what works and not in a dialogue format. But also because vivid and hopefully entertaining "lessons" are easier to remember and recall. And you will find a lot of quotes in there that most people haven't read before.

I wanted to write a book like this to reinforce a couple of concepts in my head. So even if some of the text sometimes comes out like advice to the reader, I always think about what the mathematician Gian-Carlo Rota once said, *"The advice we give others is the advice that we ourselves need."*

How do you define Mental Models?

Some kind of representation that describes how reality is (as it is known today) – a principle, an idea, basic concepts, something that works or not – that I have in my head that helps me know what to do or not. Something that has stood the test of time.

For example, some timeless truths are:

- Reality is that complete competitors – same product/niche/territory – cannot coexist (Competitive exclusion principle). What works is going where there is no or very weak competition + differentiation/advantages that others can't copy (assuming of course we have something that is needed/wanted now and in the future)
- Reality is that we get what we reward for. What works is making sure we reward for what we want to achieve.

I favor underlying principles and notions that I can apply broadly to different and relevant situations. Since some models don't resemble reality, the word "model" for me is more of an illustration/story of an underlying concept, trick, method, what works etc. that agrees with reality (as Munger once said, *"Models which underlie reality"*) and help me remember and more easily make associations.

But I don't judge or care how others label it or do it – models, concepts, default positions ... The important thing is that whatever we use, it reflects and agrees with reality and that it works for us to help us understand or explain a situation or know what to do or not do.

Useful and good enough guide me. I am pretty pragmatic – whatever works is fine. I follow Deng Xiaoping, *"I don't care whether the cat is black or white as long as it catches mice."* As Feynman said, *"What is the best method to obtain the solution to a problem? The answer is, any way that works."*

I'll tell you about a thing Feynman said on education which I remind myself of from time to time in order not to complicate things (from Richard P. Feynman, Michael A. Gottlieb, Ralph Leighton, Feynman's Tips on Physics: A Problem-Solving Supplement to the Feynman Lectures on Physics):

"There's a round table on three legs. Where should you lean on it, so the table will be the most unstable?"

The student's solution was, "Probably on top of one of the legs, but let me see: I'll calculate how much force will produce what lift, and so on, at different places."

Then I said, "Never mind calculating. Can you imagine a real table?"

"But that's not the way you're supposed to do it!"

"Never mind how you're supposed to do it; you've got a real table here with the various legs, you see? Now, where do you think you'd lean? What would happen if you pushed down directly over a leg?"

"Nothin'!"

I say, "That's right; and what happens if you push down near the edge, halfway between two of the legs?"

"It flips over!"

I say, "OK! That's better!"

The point is that the student had not realized that these were not just mathematical problems; they described a real table with legs. Actually, it wasn't a real table, because it was perfectly circular, the legs were straight up and down, and so on. But it nearly described, roughly speaking, a real table, and from knowing what a real table does, you can get a very good idea of what this table does without having to calculate anything – you know darn well where you have to lean to make the table flip over. So, how to explain that, I don't know! But once you get the idea that the problems are not mathematical problems but physical problems, it helps a lot.

Anyway, that's just two ways of solving this problem. There's no unique way of doing any specific problem. By greater and greater ingenuity, you can find ways that require less and less work, but that takes experience.

Which mental models "carry the most freight?" (Related follow up: Which concepts from Buffett/Munger/Mental Models do you find yourself referring to or appreciating most frequently?)

Ideas from biology and psychology since many stupidities are caused by not understanding human nature (and you get illustrations of this nearly every day). And most of our tendencies were already known by the classic writers (Publius Syrus, Seneca, Aesop, Cicero etc.)

Others that I find very useful both in business and private is the ideas of Quantification (without the fancy math), Margin of safety, Backups, Trust, Constraints/Weakest link, Good or Bad Economics slash Competitive advantage, Opportunity cost, Scale effects. I also think Keynes idea of changing your mind when you get new facts or information is very useful.

But since reality isn't divided into different categories but involves a lot of factors interacting, I need to synthesize many ideas and concepts.

Are there any areas of the mental models approach you feel are misunderstood or misapplied?

I don't know about that but what I often see among many smart people agrees with Munger's comment: "All this stuff is really quite obvious and yet most people don't really know it in a way where they can use it."

Anyway, I believe if you really understand an idea and what it means – not only memorizing it – you should be able to work out its different applications and functional equivalents. Take a simple big idea – think on it – and after a while you see its wider applications. To use Feynman's advice, "It is therefore of first-rate importance that you know how to "triangulate" – that is, to know how to figure something out from what you already know." As a good friend says, "Learn the basic ideas, and the rest will fill itself in. Either you get it or you don't."

Most of us learn and memorize a specific concept or method etc. and learn about its application in one situation. But when the circumstances change we don't know what to do and we don't see that the concept may have a wider application and can be used in many situations.

Take for example one big and useful idea – Scale effects. That the scale of size, time and outcomes changes things – characteristics, proportions, effects, behavior...and what is good or not must be tied to scale. This is a very fundamental idea from math. Munger described some of this idea's usefulness in his worldly wisdom speech. One effect from this idea I often see people miss and I believe is important is group size and behavior. That trust, feeling of affection and altruistic actions breaks down as group size increases, which of course is important to know in business settings. I wrote about this in Seeking Wisdom (you can read more if you type in Dunbar Number on Google search). I know of some businesses that understand the importance of this and split up companies into smaller ones when they get too big (one example is Semco).

Another general idea is "Gresham's Law" that can be generalized to any process or system where the bad drives out the good. Like natural selection or "We get what we select for" (and as Garrett Hardin writes, "The more general principle is: We get whatever we reward for).

While we are on the subject of mental models etc., let me bring up another thing that distinguishes the great thinkers from us ordinary mortals. Their ability to quickly assess and see the essence of a situation – the critical things that really matter and what can be ignored. They have a clear notion of what they want to achieve or avoid and then they have this ability to zoom in on the key factor(s) involved.

One reason to why they can do that is because they have a large repertoire of stored personal and vicarious experiences and concepts in their heads. They are masters at pattern recognition and connection. Some call it intuition but as Herbert Simon once said, "*The situation has provided a cue; this cue has given the expert access to information stored in memory, and the information provides the answer. Intuition is nothing more and nothing less than recognition.*"

It is about making associations. For example, roughly like this:

Situation X Association (what does this remind me of?) to experience, concept, metaphor, analogy, trick, filter... (Assuming of course we are able to see the essence of the situation) What counts and what doesn't? What works/not? What to do or what to explain?

Let's take employing someone as an example (or looking at a business proposal). This reminds me of one key factor – trustworthiness and Buffett's story, "If you're looking for a manager, find someone who is intelligent, energetic and has integrity. If he doesn't have the last, make sure he lacks the first two."

I believe Buffett and Munger excel at this – they have seen and experienced so much about what works and not in business and behavior.

Buffett referred to the issue of trust, chain letters and pattern recognition at the latest annual meeting:

You can get into a lot of trouble with management that lacks integrity... If you've got an intelligent, energetic guy or woman who is pursuing a course of action, which gets put on the front page it could make you very unhappy. You can get into a lot of trouble. ..We've seen patterns...Pattern recognition is very important in evaluating humans and businesses. Pattern recognition isn't one hundred percent and none of the patterns exactly repeat themselves, but there are certain things in business and securities markets that we've seen over and over and frequently come to a bad end but frequently look extremely good in the short run. One which I talked about last year was the chain letter scheme. You're going to see chain letters for the rest of your life. Nobody calls them chain letters because that's a connotation that will scare you off but they're disguised as chain letters and many of the schemes on Wall Street, which are designed to fool people, have that particular aspect to it...There were patterns at Valeant certainly...if you go and watch the Senate hearings, you will see there are patterns that should have been picked up on.

This is what he wrote on chain letters in the 2014 annual report:

In the late 1960s, I attended a meeting at which an acquisitive CEO bragged of his "bold, imaginative accounting." Most of the analysts listening responded with approving nods, seeing themselves as having found a manager whose forecasts were certain to be met, whatever the business results might be. Eventually, however, the clock struck twelve, and everything turned to pumpkins and mice. Once again, it became evident that business models based on the serial issuances of overpriced shares – just like chain-letter models – most assuredly redistribute wealth, but in no way create it. Both phenomena, nevertheless, periodically blossom in our country – they are every promoter's dream – though often they appear in a carefully-crafted disguise. The ending is always the same: Money flows from the gullible to the fraudster. And with stocks, unlike chain letters, the sums hijacked can be staggering.

And of course, the more prepared we are or the more relevant concepts and "experiences" we have in our heads, the better we all will be at this. How do we get there? Reading, learning and practice so we know it "fluently." There are no shortcuts. We have to work at it and apply it to the real world.

As a reminder to myself so I understand my limitation and "circle", I keep a paragraph from Munger's USC Gould School of Law Commencement Address handy so when I deal with certain issues, I don't fool myself into believing I am Max Planck when I'm really the Chauffeur:

In this world I think we have two kinds of knowledge: One is Planck knowledge, that of the people who really know. They've paid the dues, they have the aptitude. Then we've got chauffeur knowledge. They have learned to prattle the talk. They may have a big head of hair. They often have fine timbre in their voices. They make a big impression. But in the end what they've got is chauffeur knowledge masquerading as real knowledge.

Which concepts from Buffett/Munger/Mental Models do you find most counterintuitive?

One trick or notion I see many of us struggling with because it goes against our intuition is the concept of inversion – to learn to think “in negatives” which goes against our normal tendency to concentrate on for example, what we want to achieve or confirmations instead of what we want to avoid and disconfirmations. Another example of this is the importance of missing confirming evidence (I call it the “Sherlock trick”) – that negative evidence and events that don’t happen, matter when something implies they should be present or happen.

Another example that is counterintuitive is Newton’s 3d law that forces work in pairs. One object exerts a force on a second object, but the second object also exerts a force equal and opposite in direction to the force acting on it – the first object. As Newton wrote, “If you press a stone with your finger, the finger is also pressed by the stone.” Same as revenge (reciprocation).

Who are some of the non-obvious, or under-the-radar thinkers that you greatly admire?

One that immediately comes to mind is one I have mentioned in the introduction in two of my books is someone I am fortunate to have as a friend – Peter Kaufman. An outstanding thinker and a great businessman and human being. On a scale of 1 to 10, he is a 15.

What have you come to appreciate more with Buffett/Munger’s lessons as you’ve studied them over the years?

Their ethics and their ethos of clarity, simplicity and common sense. These two gentlemen are outstanding in their instant ability to exclude bad ideas, what doesn’t work, bad people, scenarios that don’t matter, etc. so they can focus on what matters. Also my amazement that their ethics and ideas haven’t been more replicated. But I assume the answer lies in what Munger once said, “The reason our ideas haven’t spread faster is they’re too simple.” This reminds me something my father-in-law once told me (a man I learnt a lot from) – the curse of knowledge and the curse of academic title. My now deceased father-in-law was an inventor and manager. He did not have any formal education but was largely self-taught. Once a big corporation asked for his services to solve a problem their 60 highly educated engineers could not solve. He solved the problem. The engineers said, “It can’t be that simple.” It was like they were saying that, “Here we have 6 years of school, an academic title, lots of follow up education. Therefore an engineering problem must be complicated”. Like Buffett once said of Ben Graham’s ideas, “I think that it comes down to those ideas – although they sound so simple and commonplace that it kind of seems like a waste to go to school and get a PhD in Economics and have it all come back to that. It’s a little like spending eight years in divinity school and having somebody tell you that the 10 commandments were all that counted. There is a certain natural tendency to overlook anything that simple and important.”

(I must admit that in the past I had a tendency to be extra drawn to elegant concepts and distracting me from the simple truths.)

What things have you come to understand more deeply in the past few years?

- That I don’t need hundreds of concepts, methods or tricks in my head – there are a few basic, time-filtered fundamental ones that are good enough. As Munger says, “The more basic knowledge you have the less new knowledge you have to get.” And when I look at something “new”, I try to connect it to something I already understand and if possible get a wider application of an already existing basic concept that I already have in my head.
- Neither do I have to learn everything to cover every single possibility – not only is it impossible but the big reason is well explained by the British statistician George Box. He said that we shouldn’t be preoccupied with optimal or best procedures but good enough over a range of possibilities likely to happen in practice – circumstances which the world really present to us.

- The importance of “Picking my battles” and focus on the long-term consequences of my actions. As Munger said, “A majority of life’s errors are caused by forgetting what one is really trying to do.”
- How quick most of us are in drawing conclusions. For example, I am often too quick in being judgmental and forget how I myself behaved or would have behaved if put in another person’s shoes (and the importance of seeing things from many views).
- That I have to “pick my poison” since there is always a set of problems attached with any system or approach – it can’t be perfect. The key is try to move to a better set of problems one can accept after comparing what appear to be the consequences of each.
- How efficient and simplified life is when you deal with people you can trust. This includes the importance of the right culture.
- The extreme importance of the right CEO – a good operator, business person and investor.
- That luck plays a big role in life.
- That most predictions are wrong and that prevention, robustness and adaptability is way more important. I can’t help myself – I have to add one thing about the people who give out predictions on all kinds of things. Often these are the people who live in a world where their actions have no consequences and where their ideas and theories don’t have to agree with reality.
- That people or businesses that are foolish in one setting often are foolish in another one (“The way you do anything, is the way you do everything”).
- Buffett’s advice that “A checklist is no substitute for thinking.” And that sometimes it is easy to overestimate one’s competency in a) identifying or picking what the dominant or key factors are and b) evaluating them including their predictability. That I believe I need to know factor A when I really need to know B – the critical knowledge that counts in the situation with regards to what I want to achieve.
- Close to this is that I sometimes get too involved in details and can’t see the forest for the trees and I get sent up too many blind alleys. Just as in medicine where a whole body scan sees too much and sends the doctor up blind alleys.
- The wisdom in Buffett’s advice that “You only have to be right on a very, very few things in your lifetime as long as you never make any big mistakes...An investor needs to do very few things right as long as he or she avoids big mistakes.”

What’s the best investment of time/effort/money that you’ve ever made?

The best thing I have done is marrying my wife. As Buffett says and it is so so true, “Choosing a spouse is the most important decision in your life...You need everything to be stable, and if that decision isn’t good, it may affect every other decision in life, including your business decisions...If you are lucky on health and...on your spouse, you are a long way home.”

A good “investment” is taking the time to continuously improve. It just takes curiosity and a desire to know and understand – real interest. And for me this is fun.

What does your typical day look like? (How much time do you spend reading... and when?)

Every day is a little different but I read every day.

What book has most impacted your life?

There is not one single book or one single idea that has done it. I have picked up things from different books (still do). And there are different books and articles that made a difference during different periods of my life. Meeting and learning from certain people and my own practical experiences has been more important in my development. As an example – When I was in my 30s a good friend told me something that has been very useful in looking at products and businesses. He said I should always ask who the real customer is: *“Who ultimately decides what to buy and what are their decision criteria and how are they measured and rewarded and who pays?”*

But looking back, if I have had a book like Poor Charlie’s Almanack when I was younger I would have saved myself some misery. And of course, when it comes to business, managing and investing, nothing beats learning from Warren Buffett’s Letters to Berkshire Hathaway Shareholders.

Another thing I have found is that it is way better to read and reread fewer books but good and timeless ones and then think. Unfortunately many people absorb too many new books and information without thinking.

Let me finish this with some quotes from my new book that I believe we all can learn from:

- “There’s no magic to it...We haven’t succeeded because we have some great, complicated systems or magic formulas we apply or anything of the sort. What we have is just simplicity itself.” – Buffett
- “Our ideas are so simple that people keep asking us for mysteries when all we have are the most elementary ideas...There’s nothing remarkable about it. I don’t have any wonderful insights that other people don’t have. Just slightly more consistently than others, I’ve avoided idiocy...It is remarkable how much long-term advantage people like us have gotten by trying to be consistently not stupid, instead of trying to be very intelligent.” – Munger
- “It really is simple – just avoid doing the dumb things. Avoiding the dumb things is the most important.” – Buffett

Finally, I wish you and your readers an excellent day – Everyday!

88. Using Multidisciplinary Thinking to Approach Problems in a Complex World

Complex outcomes in human systems are a tough nut to crack when it comes to deciding what's really true. Any phenomena we might try to explain will have a host of competing theories, many of them seemingly plausible.

So how do we know what to go with?

One idea is to take a nod from the best. One of the most successful “explainers” of human behavior has been the cognitive psychologist Steven Pinker. His books have been massively influential, in part because they combine scientific rigor, explanatory power, and plainly excellent writing.

What's unique about Pinker is the range of sources he draws on. His book The Better Angels of Our Nature, a cogitation on the decline in relative violence in recent human history, draws on ideas from evolutionary psychology, forensic anthropology, statistics, social history, criminology, and a host of other fields. Pinker, like Vaclav Smil and Jared Diamond, is the opposite of the man with a hammer, ranging over much material to come to his conclusions.

In fact, when asked about the progress of social science as an explanatory arena over time, Pinker credited this cross-disciplinary focus:

Because of the unification with the sciences, there are more genuinely explanatory theories, and there's a sense of progress, with more non-obvious things being discovered that have profound implications.

But, even better, Pinker gives out an outline for how a multidisciplinary thinker should approach problems in a complex world.

Here's the issue at stake: When we're viewing a complex phenomena—say, the decline in certain forms of violence in human history—it can be hard to come up with a rigorous explanation. We can't just set up repeated lab experiments and vary the conditions of human history to see what pops out, as with physics or chemistry.

So out of necessity, we must approach the problem in a different way.

In the above referenced interview, Pinker gives a wonderful example how to do it:

Note how he carefully “cross-checks” from a variety of sources of data, developing a 3D view of the landscape he's trying to assess:

Pinker: Absolutely, I think most philosophers of science would say that all scientific generalizations are probabilistic rather than logically certain, more so for the social sciences because the systems you are studying are more complex than, say, molecules, and because there are fewer opportunities to intervene experimentally and to control every variable. But the existence of the social sciences, including psychology, to the extent that they have discovered anything, shows that, despite the uncontrollability of human behavior, you can make some progress: you can do your best to control the nuisance variables that are not literally in your control; you can have analogues in a laboratory that simulate what you're interested in and impose an experimental manipulation.

You can be clever about squeezing the last drop of causal information out of a correlational data set, and you can use converging evidence, the qualitative narratives of traditional history in combination with quantitative data sets and regression analyses that try to find patterns in them. But I also go to traditional historical narratives, partly as a sanity check. If you're just manipulating numbers, you never know whether you've wandered into some preposterous conclusion by taking numbers too seriously that couldn't possibly reflect reality. Also, it's the narrative history that provides hypotheses that can then be tested. Very often a historian comes up with some plausible causal story, and that gives the social scientists something to do in squeezing a story out of the numbers.

Warburton: I wonder if you've got an example of just that, where you've combined the history and the social science?

Pinker: One example is the hypothesis that the Humanitarian Revolution during the Enlightenment, that is, the abolition of slavery, torture, cruel punishments, religious persecution, and so on, was a product of an expansion of empathy, which in turn was fueled by literacy and the consumption of novels and journalistic accounts. People read what life was like in other times and places, and then applied their sense of empathy more broadly, which gave them second thoughts about whether it's a good idea to disembowel someone as a form of criminal punishment. So that's a historical hypothesis. Lynn Hunt, a historian at the University of California–Berkeley, proposed it, and there are some psychological studies that show that, indeed, if people read a first-person account by someone unlike them, they will become more sympathetic to that individual, and also to the category of people that that individual represents.

So now we have a bit of experimental psychology supporting the historical qualitative narrative. And, in addition, one can go to economic historians and see that, indeed, there was first a massive increase in the economic efficiency of manufacturing a book, then there was a massive increase in the number of books published, and finally there was a massive increase in the rate of literacy. So you've got a story that has at least three vertices: the historian's hypothesis; the economic historians identifying exogenous variables that changed prior to the phenomenon we're trying to explain, so the putative cause occurs before the putative effect; and then you have the experimental manipulation in a laboratory, showing that the intervening link is indeed plausible.

Pinker is saying, Look we can't just rely on "plausible narratives" generated by folks like the historians. There are too many possibilities that could be correct.

*Nor can we rely purely on correlations (i.e., the rise in literacy statistically tracking the decline in violence) — they don't necessarily offer us a causative explanation. (Does the rise in literacy *cause* less violence, or is it vice versa? Or, does a third factor cause both?) However, if we layer in some other known facts from areas we can experiment on — say, psychology or cognitive neuroscience — we can sometimes establish the causal link we need or, at worst, a better hypothesis of reality.*

In this case, it would be the finding from psychology that certain forms of literacy do indeed increase empathy (for logical reasons).

*Does this method give us absolute proof? No. However, it does allow us to *propose* and then test, re-test, alter, and strengthen or ultimately reject a hypothesis. (In other words, rigorous thinking.)*

We can't stop here though. We have to take time to examine competing hypotheses — there may be a better fit. The interviewer continues on asking Pinker about this methodology:

Warburton: And so you conclude that the de-centering that occurs through novel-reading and first-person accounts probably did have a causal impact on the willingness of people to be violent to their peers?

Pinker: That's right. And, of course, one has to rule out alternative hypotheses. One of them could be the growth of affluence: perhaps it's simply a question of how pleasant your life is. If you live a longer and healthier and more enjoyable life, maybe you place a higher value on life in general, and, by extension, the lives of others. That would be an alternative hypothesis to the idea that there was an expansion of empathy fueled by greater literacy. But that can be ruled out by data from economic historians that show there was little increase in affluence during the time of the Humanitarian Revolution. The increase in affluence really came later, in the 19th century, with the advent of the Industrial Revolution.

Let's review the process that Pinker has laid out, one that we might think about emulating as we examine the causes of complex phenomena in human systems:

1. We observe an interesting phenomenon in need of explanation, one we feel capable of exploring.

2. We propose and examine competing hypotheses that would explain the phenomena (set up in a falsifiable way, in harmony with the divide between science and pseudoscience laid out for us by the great Karl Popper).
3. We examine a cross-section of: Empirical data relating to the phenomena; sensible qualitative inference (from multiple fields/disciplines, the more fundamental the better), and finally; “Demonstrable” aspects of nature we are nearly certain about, arising from controlled experiment or other rigorous sources of knowledge ranging from engineering to biology to cognitive neuroscience.

What we end up with is not necessarily a bulletproof explanation, but probably the best we can do if we think carefully. A good cross-disciplinary examination with quantitative and qualitative sources coming into equal play, and a good dose of judgment, can be far more rigorous than the gut instinct or plausible nonsense type stories that many of us lazily spout.

A Word of Caution

Although Pinker’s “multiple vertices” approach to problem solving in complex domains can be powerful, we always have to be on guard for phenomena that we simply cannot explain at our current level of competence: We must have a “too hard” pile when competing explanations come out “too close to call” or we otherwise feel we’re outside of our circle of competence. Always tread carefully and be sure to follow Darwin’s Golden Rule: Contrary facts are more important than confirming ones. Be ready to change your mind, like Darwin, when the facts don’t go your way.

89. The Green Lumber Fallacy: The Difference between Talking and Doing

“Clearly, it is unrigorous to equate skills at doing with skills at talking..”

— Nassim Taleb

“All that glitters is not gold,” the saying goes. The aesthetics of things often fool us. People we call ignorant might not be ignorant. People we call smart might not be smart. The Green Lumber Fallacy teaches us that the real world doesn’t always match our stories. The real causative factors of success are often hidden from us.

If you’re familiar with evolutionary theory, you know that populations of organisms are constantly subjected to “selection pressures” — the rigors of their environment which lead to certain traits being favored and passed down to their offspring and others being thrown into the evolutionary dustbin.

Biologists dub these advantages in reproduction “*fitness*” — as in, the famously lengthening of giraffe necks gave them greater “fitness” in their environment because it helped them reach high up, untouched leaves. Fitness is generally a relative concept: Since organisms must compete for scarce resources, their fitnesses is measured in the sense of giving a reproductive advantage over one another.

A trait that might provide great fitness in one environment may be useless or even disadvantageous in another. (Imagine draining a pond: Any fitness advantages held by a really incredible fish becomes instantly worthless without water.) Traits also relate to circumstance. An advantage at one time could be a disadvantage at another and vice versa. Nature doesn’t argue, it just tests over and over.

This makes fitness an all-important concept in biology: Traits are selected for if they provide fitness to the organism within a given environment.

The Black Swan author Nassim Taleb has an interesting take on fitness and selection in the real world that boils down to: People who are good “doers” and people who are good “talkers” are often selected for different traits. Be careful not to mix them up.

In his book Antifragile, Taleb uses this idea to invoke a heuristic he’d once used when hiring traders on Wall Street:

The more interesting their conversation, the more cultured they are, the more they will be trapped into thinking that they are effective at what they are doing in real business (something psychologists call the halo effect, the mistake of thinking that skills in, say, skiing translate unfailingly into skills in managing a pottery workshop or a bank department, or that a good chess player would be a good strategist in real life). Clearly, it is unrigorous to equate skills at doing with skills at talking. My experience of good practitioners is that they can be totally incomprehensible—they do not have to put much energy into turning their insights and internal coherence into elegant style and narratives. Entrepreneurs are selected to be doers, not thinkers, and doers do, they don't talk, and it would be unfair, wrong, and downright insulting to measure them in the talk department.

The selection pressures for an entrepreneur are very different from those on a corporate manager or bureaucrat. Entrepreneurs and risk-takers succeed or fail not so much on their ability to talk, explain, and rationalize as their ability to advantageously diverge from the crowd and get things done. While talking and doing can go together, they frequently don't. When you think about it, there's no reason great intellectualizing and great doing must go together: Being able to hack together an incredible piece of code gives you great fitness in the world of software development while doing great theoretical computer science probably gives you better fitness in academia. The two skills don't have to be connected. Great economists don't usually make great investors. But we often confuse the two realms.

We're tempted to think that a great investor must be fluent in behavioral economics or a great CEO fluent in McKinsey-esque management narratives, but in the real world, we see this intuition is constantly proved incorrect.

The investor Walter Schloss worked from 9-5, barely left his office, and wasn't considered an entirely high IQ man, but he compiled one of the great investment records of all time. A young Mark Zuckerberg could hardly be described as a prototypical manager or businessperson, yet somehow built one of the most profitable companies in the world by finding others that complemented his weaknesses.

Our narratives about the type of knowledge or experience we must have or the type of people we must be in order to become successful are often quite wrong; in fact, they border on naive. We think people who *talk well* can *do well*, and vice versa. This is simply not always so.

We won't claim that great doers *cannot be* great talkers, rationalizers, or intellectuals. Sometimes they are. But if you're seeking to understand the world properly, it's good to understand that the two traits are not always co-located.

Success, especially in some "narrow" area like plumbing, programming, trading, or marketing, is often achieved by rather non-intellectual folks. Their evolutionary fitness doesn't come from the ability to talk but do.

The Green Lumber Fallacy

Taleb calls this divergence the Green Lumber Fallacy, after a story in the book *What I Learned Losing a Million Dollars*.

As Taleb describes it in *Antifragile*:

*In one of the rare noncharlatanic books in finance, descriptively called *What I Learned Losing a Million Dollars*, the protagonist makes a big discovery. He remarks that a fellow named Joe Siegel, one of the most successful traders in a commodity called "green lumber," actually thought it was lumber painted green (rather than freshly cut lumber, called green because it had not been dried). And he made it his profession to trade the stuff! Meanwhile the narrator was into grand intellectual theories and narratives of what caused the price of commodities to move, and went bust.*

It is not just that the successful expert on lumber was ignorant of central matters like the designation “green.” He also knew things about lumber that nonexperts think are unimportant. People we call ignorant might not be ignorant.

The fact that predicting the order flow in lumber and the usual narrative had little to do with the details one would assume from the outside are important. People who do things in the field are not subjected to a set exam; they are selected in the most non-narrative manner — nice arguments don’t make much difference. Evolution does not rely on narratives, humans do. Evolution does not need a word for the color blue.

So let us call the green lumber fallacy the situation in which one mistakes a source of visible knowledge — the greenness of lumber — for another, less visible from the outside, less tractable, less narratable.

The main takeaway is that the real causative factors of success are often hidden from us. We think that knowing the intricacies of green lumber are more important than keeping a close eye on the order flow. We seduce ourselves into overestimating the impact of our intellectualism and then wonder why “idiots” are getting ahead.

But for “skin in the game” operations, selection and evolution don’t care about great talk and ideas unless they translate into results. They care what you do with the thing more than that you *know* the thing. They care about actually avoiding risk rather than your extensive knowledge of risk management theories. (Of course, in many areas of modernity *there is no skin in the game*, so talking and rationalizing can be and frequently are selected for.)

As Taleb did with his hiring heuristic, this should teach us to be a little skeptical of taking good talkers at face value, and to be a little skeptical when we see “unexplainable” success in someone we consider “not as smart.” There might be a disconnect we’re not seeing because we’re seduced by a narrative. (A problem someone like Lee Kuan Yew avoided by focusing exclusively on what worked.)

We don’t have to give up our intellectual pursuits in order to appreciate this nugget of wisdom; Taleb is right, but it’s also true that combining the rigorous, skeptical knowledge of “what actually works” with an ever-improving theory structure of the world might be the best combination of all — selected for in many more environments than simple *git-er-done* ability, which can be extremely domain and environment dependent. (The green lumber guy might not have been much good outside the trading room.)

90. Batesian Mimicry: Why Copycats Are Successful

One of our first interview guests for The Knowledge Project was the former NFL executive Michael Lombardi. In our interview, we discussed topics ranging from the nature of leadership to decision making in a football context. Mike is one of the wisest thinkers associated with the game.

We heard Mike on an NFL podcast recently, and in a brief clip you can listen to here, Mike makes a fascinating comment on differentiating between a Mimic and the Real Thing:

“There’s two kinds of snakes you come across. There’s the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it’s venomous, it can kill you in a minute. The Mexican Milk Snake can’t do anything to you; it’s an impostor.”

Mike got the idea from my friend and CEO of Glenair, Peter Kaufman. Following Mike’s lead, we chose to dig in a little further.

Turns out there are a *host* of Coral Snake Mimics, all designed to look exactly as fierce as the true bad guys. Besides the Mexican Milk Snake, there is the Scarlet King Snake, the Florida Scarlet Snake, and the California Mountain Kingsnake. (At least.)

For an example, here are the Texas Coral Snake on the left and the Mexican Milk Snake on the right. Pretty damn close!

According to Wikipedia, the Texas Coral Snake's venom is a "powerful neurotoxin, causing neuromuscular dysfunction", and terrifyingly describes its bite as coming from "a pair of hollow, small, fixed fangs in the front of its upper jaw, through which the venom is injected and encouraged via a chewing motion. Due to this method of venom delivery, a coral snake must bite and hold on for a brief time to deliver a significant amount of venom..." The Milk Snake, on the other hand, is described as a pretty ideal pet: "The Mexican Milk Snake adapts well to captive care, and its smaller size and striking colorations can make it an attractive choice for a pet snake. They are normally docile, and not typically apt to bite or expel musk."

So, how is it that these two look alike? It's due to a phenomenon called Batesian Mimicry. In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the "models") were able to operate freely and relatively unmolested, there had also developed a "mimic" population of butterflies which wasn't toxic at all, yet still went untouched!

In fact, biologists eventually figured out that the more toxic and dangerous the "model" was and the more frequently they appeared in the local population, the easier it was for its "mimics" to get by! Predators simply wouldn't take the risk of mixing up the two. If there aren't as many "models" around or they aren't that dangerous, the mimics have a harder time.

This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or "pretenders to the throne" are often very effective, very convincing "mimics" of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs.

We see a very Batesian effect at work: The more impressive the "model," the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many "future" Warren Buffetts. For every Steve Jobs, there have been many "next" Steve Jobs'. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit.

It seems almost a law of nature that success will be copied, sometimes in a very disgraceful way. (Charlie Munger thinks that the fundamental algorithm of life is "Repeat what works.")

Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry — even in ourselves.

This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself.

The real thing knows a fake. Charlie Munger once commented on this in relation to the field of money management:

"It's very hard to tell the difference between a good money manager and someone who just has the patter down. If you aren't a good money manager yourself, rather than trying to pick one, you're probably better off with a low cost index fund. 'It takes one to know one'."

An insight this good is only possible through continued study across the largest and most relevant fields of study. Peter got this idea by studying biology, a field full of incredible insight but, strangely underappreciated by most "non-biologists". It's not just ideas about predators and prey, but niches, competition, co-evolutionary arms races and a whole host of others which give us massive insight into the human world.

Peter realized that studying across fields like biology and physics is something like buying an index fund: It works because you capture *all* the important companies traded on the public exchange, not just a select few. That means you capture the massive winners, which tend to greatly outweigh the failures.

Studying across *all* of the important fields gives you the same advantage, except it's even better: If an index fund buys a new position, it must sell something to do so; consequently, the "big winners" can only impact your portfolio in a limited way. But if you come to understand a new Great Idea, you don't have to give up the ones you already know! This is a great advantage.

And so it's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

91. Immigration, Extinction, and Island Equilibrium

Equilibrium is an important concept that permeates many disciplines. In chemistry we think about the point where the rate of *forward reaction* is equal to the rate of *backward reaction*. In economics we think of the point where *supply* equals *demand*. In physics we can see how *gravity* is balanced by *forward velocity* to create things like planetary orbits.

No matter which discipline we are examining, the core idea remains the same: Equilibrium is a state where opposing forces are balanced.

In biology, equilibrium is so important that it can mean the difference between life or death; for a species, it can decide whether they will thrive or become extinct.

In The Song of the Dodo, David Quammen dives into how equilibrium affects a species' ability to survive, and how it impacts our ability to save animals on the brink of extinction.

Historically, the concept of island equilibrium was studied with a focus on the interplay between evolution (as the additive) and extinction (as the subtractive). It was believed that speciation, the process where one species becomes two or more species, caused any increase in the number of inhabitants on an island. In this view, the insularity of islands created a remoteness that could only be overcome by the long processes of evolution. However, Robert MacArthur and E.O. Wilson, the co-authors of the influential Theory of Island Biogeography, realized that habitats would show a tendency towards equilibrium much sooner than could be accounted for by speciation. They argued the ongoing processes that most influenced this balance were immigration and extinction.

The type of extinctions we're referring to in this case are local extinctions, specific to the island in question. A species can go extinct on a particular island and yet be thriving elsewhere; it depends on local conditions.

As for immigration, it's just what you'd expect: The movement of species from one place to another. Island immigration describes the many ingenious ways in which plants, animals, and insects travel to islands. For instance, not only will insects hitch rides on birds and debris (man made or natural, think garbage and sticks/uprooted seaweed), animals will do the same if the debris is massive enough.

Seeds, meanwhile, make the trip in the feces of birds, which helps to introduce new plant species to the island, while highly motivated swimmers (escapees of natural disasters/predators/famine) and hitchhikers on human ships (think rats) make it over in their own unusual ways.

We can plot this process of immigration and extinction *graphically*, in a way you're probably familiar with. Quammen explains:

The decrease in immigration rate and the increase in extinction rate are graphed not against elapsed time but against the number of species present on a given island. As an island fills up with species, immigration declines and extinction increases, until they offset each other at an equilibrium level. At that level, the rate of continuing immigration is just canceled by the rate of continuing extinction, and there is no net gain or loss of species. The phenomenon of offsetting increase and decrease – the change of identities on the roster of species – is known as turnover. One species of butterfly arrives, another species of butterfly dies out, and in the aftermath the island has the same number of butterfly species as before. Equilibrium with turnover.

So while the specific species inhabiting the island will change over time, the numbers will tend to roll towards a balanced point where the two curves intersect.

Of course, not all equilibrium graphs will look the like one above. Indeed, MacArthur and Wilson hoped this theory would be used not just to explain equilibriums, but to also help predict potential issues.

When either curve is especially steep – reflecting the fact that immigration decreases especially sharply or extinction increases especially sharply – their crossing point shifts leftward, toward zero. The shift means that, at equilibrium, in this particular set of circumstances, there will be relatively few resident species.

In other words, high extinction and low immigration yield an impoverished ecosystem. To you and me it's a dot in Cartesian space, but to an island it represents destiny.

There are two key ideas that can help us understand the equilibrium point on a given island.

First, the concept of species-area relationship: We see a larger number of a given species on larger islands and a smaller number of a given species on smaller islands.

Second, the concept of species quantity on remote islands: Immigration is much more difficult the further away an island is from either a mainland or a cluster of other islands, meaning that fewer species will make it there.

In other words, size and remoteness are directly correlated to the fragility of any given species inhabiting an island.

Equilibrium, immigration, evolution, extinction – these are all ideas that bleed into so many more areas than biogeography. What happens to groups when they are isolated? Jared Diamond had some interesting thoughts on that. What happens to products or businesses which don't keep up with co-evolution? They go extinct due to the Red Queen Effect. What happens to our mind and body when we feel off balance? Our life is impoverished. Reading a book like The Song of the Dodo helps us to better understand these key concepts which, in turn, helps us more fundamentally understand the world.

92. Principles for an Age of Acceleration

We live in an age where technology is developing at a rate faster than what any individual can keep up with. To survive in an age of acceleration, we need a new way of thinking about technology.

MIT Media Lab is a creative nerve center where great ideas like One Laptop per Child, LEGO Mindstorms, and Scratch programming language have emerged.

Its director, Joi Ito, has done a lot of thinking about how prevailing systems of thought will not be the ones to see us through the coming decades. In his book Whiplash: How to Survive our Faster Future, he notes that sometime late in the last century, technology began to outpace our ability to understand it.

We are blessed (or cursed) to live in interesting times, where high school students regularly use gene editing techniques to invent new life forms, and where advancements in artificial intelligence force policymakers to contemplate widespread, permanent unemployment. Small wonder our old habits of mind—forged in an era of coal, steel, and easy prosperity—fall short. The strong no longer necessarily survive; not all risk needs to be mitigated; and the firm is no longer the optimum organizational unit for our scarce resources.

Ito's ideas are not specific to our moment in history, but adaptive responses to a world with certain characteristics:

1. Asymmetry

In our era, effects are no longer proportional to the size of their source. The biggest change-makers of the future are the small players: “start-ups and rogues, breakaways and indie labs.”

2. Complexity

The level of complexity is shaped by four inputs, all of which are extraordinarily high in today's world: heterogeneity, interconnection, interdependency and adaptation.

3. Uncertainty

“Not knowing is okay. In fact, we've entered an age where the admission of ignorance offers strategic advantages over expending resources—subcommittees and think tanks and sales forecasts—toward the increasingly futile goal of forecasting future events.”

When these three conditions are in place, certain guiding principles serve us best. In his book, Ito shares some of the maxims that organize his “anti-disciplinary” Media Lab in a complex and uncertain world.

Emergence over Authority

Complex systems show properties that their individual parts don't possess, and we call this process “emergence”. For example, life is an emergent property of chemistry. Groups of people also produce a wondrous variety of emergent behaviors—languages, economies, scientific revolutions—when each intellect contributes to a whole that is beyond the abilities of any one person.

Some organizational structures encourage this kind of creativity more than others.

Authoritarian systems only allow for incremental changes, whereas nonlinear innovation emerges from decentralized networks with a low barrier to entry. As Stephen Johnson describes in Emergence, when you plug more minds into the system, “isolated hunches and private obsessions coalesce into a new way of looking at the world, shared by thousands of individuals.”

Synthetic biology best exemplifies the type of new field that can arise from emergence. Not to be confused with genetic engineering, which modifies existing organisms, synthetic biology aims to create entirely new forms of life.

Having emerged in the era of open-source software, synthetic biology is becoming an exercise in radical collaboration between students, professors, and a legion of citizen scientists who call themselves biohackers. Emergence has made its way into the lab. As a result, the cost of sequencing DNA is plummeting at six times the rate of Moore's Law, and a large Registry of Standard Biological Parts, or BioBricks, now offers genetic components that perform well-understood functions in whatever organism is being created, like a block of Lego.

There is still a place for leaders in an organization that fosters emergence, but the role may feel unfamiliar to a manager from a traditional hierarchy. The new leader spends less time leading and more time “gardening”—pruning the hedges, watering the flowers, and otherwise getting out of the way. (As biologist Lewis Thomas puts it, a great leader must get the air right.)

Pull over Push

“Push” strategies involve directing resources from a central source to sites where, in the leader’s estimation, they are likely to be needed or useful. In contrast, projects that use “pull” strategies attract intellectual, financial and physical resources to themselves just as they are needed, rather than stockpiling them.

Ito is a proponent of the sharing economy, through which a startup might tap into the global community of freelancers and volunteers for a custom-made task force instead of hiring permanent teams of designers, programmers or engineers.

Here’s a great example:

When the Fukushima nuclear meltdown happened, Ito was living just outside of Tokyo. The Japanese government took a command-and-control (“push”) approach to the disaster, in which information would slowly climb up the hierarchy, and decisions would then be passed down stepwise to the ground-level workers.

It soon became clear that the government was not equipped to assess or communicate the radioactivity levels of each neighborhood, so Ito and his friends took the problem into their own hands. Pulling in expertise and money from far-flung scientists and entrepreneurs, they formed a citizen science group called Safecast, which built its own GPS-equipped Geiger counters and strapped them to cars for faster monitoring. They launched a website that continues to share data – more than 50 million data points so far – about local environments.

To benefit from these kinds of “pull” strategies, it pays to foster an environment that is rich with weak ties – a wide network of acquaintances from which to draw just-in-time knowledge and resources, as Ito did with Safecast.

Compasses over Maps

Detailed maps can be more misleading than useful in a fast-changing world, where a compass is the tool of choice. In the same way, organizations that plan exhaustively will be outpaced in an accelerating world by ones that are guided by a more encompassing mission.

A map implies a straightforward knowledge of the terrain, and the existence of an optimum route; the compass is a far more flexible tool and requires the user to employ creativity and autonomy in discovering his or her own path.

One advantage to the compass approach is that when a roadblock inevitably crops up, there is no need to go back to the beginning to form another plan or draw up multiple plans for each contingency. You simply navigate around the obstacle and continue in your chosen direction.

It is impossible, in any case, to make detailed plans for a complex and creative organization. The way to set a compass direction for a company is by creating a culture—or set of mythologies—that animates the parts in a common worldview.

In the case of the MIT Media Lab, that compass heading is described in three values: “Uniqueness, Impact, and Magic”. *Uniqueness* means that if someone is working on a similar project elsewhere, the lab moves on.

Rather than working to discover knowledge for its own sake, the lab works in the service of *Impact*, through start-ups and physical creations. It was expressed in the lab’s motto “Deploy or die”, but Barack Obama suggested they work on their messaging, and Ito shortened it to “Deploy.”

The *Magic* element, though hard to define, speaks to the delight that playful originality so often awakens.

Both students and faculty at the lab are there to learn, but not necessarily to be “educated”. Learning is something you pursue for yourself, after all, whereas education is something that’s done to you. The result is “agile, scrappy, permissionless innovation”.

The new job landscape requires more creativity from everybody. The people who will be most successful in this environment will be the ones who ask questions, trust their instincts, and refuse to follow the rules when the rules get in their way.

Other principles discussed in Whiplash include Risk over Safety, Disobedience over Compliance, Practice over Theory, Diversity over Ability, Resilience over Strength, and Systems over Objects.

93. Tribal Leadership: The Key To Building Great Teams

Have you ever wondered about internal organization dynamics and why some groups of people (who aren't on the same team) are more successful than others? Why different "tribes" inside the organization seem to be at war with one another lowering performance in increasing politics? Why certain groups of people never seem to do anything? Or why its hard to move into the next level? Read on.

Tribal Leadership

Organizations are a collection of small towns wrapped into a bigger city. Each small town is full of people from slackers to sherifs. While the people in the towns are different, the roles are similar. In their book, Tribal Leadership: Leveraging Natural Groups to Build a Thriving Organization, Dave Logan, John King, and Halee Fischer-Wright, call these small towns tribes.

Tribes consist of groups of people from 20-150. (You can think of the test to identify whether someone is in your tribe as stopping to say "hello" and have a brief chat when you pass them on the street.) When the tribe approaches 150, a number that comes from Robin Dunbar's research that was popularized in The Tipping Point, it naturally splits into two.

Importantly, tribes are not (necessarily) teams. Yet tribes are how work gets done in organizations. They have the ability to render the latest corporate culture efforts from CEOs useless. "In companies," Logan and his co-authors write, "tribes decide whether the new leader is going to flourish or get taken out. They determine how much work is going to get done, and of what quality."

As you can imagine some tribes want to change the world while others are content to take a lot of coffee breaks. What compels one tribe of people to constantly evolve and move forward and another to stagnate (succumbing to the Red Queen Effect)? The leaders of the tribe.

More than others, tribal leaders influence the culture of their respective tribes. Ambitious leaders focus on growing, adapting, and upgrading the tribal culture to improve the tribes standing in the organization. If they are successful, the tribe members reward them with "cult like loyalty." (This explains the phenomenon of promotions in a lot of organizations: When the tribe leader is promoted, a lot of the tribe members follow suit.)

Organizations are the sum of the tribes. Some are moving in the same direction while others veer in another. Some tribes propel while yet others add friction. Some tribes attract talent and others eject it. Performance is set not by the individual tribe leader but by the aggregation of them.

Tribal leadership is a process not an outcome and most people are blind to the dynamics of their tribes. Like all of our mental models, when you learn to see your company as a tribe, you can't unsee it. Things just click.

Logan and his co-authors simplify the dynamics of tribal leadership into 5 stages and they arrange the tools accordingly. Each stage has different "leverage points" to move to the next stage. "Each stage," they write, "gets more done and has more fun than the one before it."

Companies are never fully in one stage. They may have various tribes in Stage Two all the way to (hopefully) Stage Five. The more tribes you have operating at higher levels the better the company's performance, at least in theory.

Every tribe has a dominant culture, which we can peg on a one-to-five scale, with the goal being stability at Stage Four, and on occasion leaps to Stage Five.

The leverage points to move from Stage Two to Stage Three is not the same as those you need at Stage Three to move to Stage Four. (A lot of business and self-help books fail to realize this point. Perspective advice is more contextual than people realize.)

Let's look at the Five Stages before looking at the leverage points.

The Five Tribal Stages

Stage One (2%): This is the "life sucks" camp. Logan and his co-authors likely this to street gangs and people that come to work with hostility and despair.

Stage Two (25%): In this stage, life doesn't suck, only your life. In this stage, Logan et al. write, people are "passively antagonistic; they cross their arms in judgment yet never really get interested enough to spark any passion. Their laughter is quietly sarcastic and resigned. The Stage Two talk is that they've seen in all before and watched it all fail. A person at Stage Two will often try to protect his or her people from the intrusion of management." This tribe is largely a collection of victims. This is what we see in Government Departments or The Office. Innovation is almost non-existent. Urgency is reserved for the coffee break. Accountability is rare.

Stage Three (49%): Moving along the continuum from "my life sucks" (Stage Two) we arrive at "I'm great (and you're not)". "Within the Stage Three culture," Logan and his coauthors write, "knowledge is power, so people hoard it, from client contacts to gossip about the company." At this Stage people need to win, especially if that means you lose. On an individual basis, these people are generally competent but form a collection of "lone warriors," who want to help but experience near continuous disappointment when "others don't have their ambition of skill." These people, however, are willing to do the work. The most common complaints for people at this level is that they are too busy, they have no time, and they have crappy support.

Stage Four (22%): This is the progress from *I'm great* (Stage Three) to *we're great* (Stage Four). The journey is not measured in equidistant miles between each stage and the gulf between Three and Four is much larger than from Two to Three. In this Stage if you take the tribe away, "the person's sense of self suffers a loss." Leaders in this Stage feel "pulled by the group." Stage Four tribes have an outside adversary (whereas those operating in Stages Two and Three often have internal ones.) "The rule for Stage Four," writes Logan et al., is "the bigger the foe, the more powerful the tribe." These tribes have little patience for the politics, personal agendas, and Office-style performance that dominate Stage Three. Like a transplant that doesn't take, the group rejects these people.

Stage Five (2%): "Stage Five's T-shirt," write Logan et al., "would read life is great." The language here is one of potential and making history. "Teams at Stage Five have produced miraculous innovations. The team that produced the first Macintosh was at Stage Five. ... This stage is pure leadership, vision, and inspiration." These teams often revert back to Stage Four to regroup before attempting to summit again.

Stage	Mood	Theme
5	Innocent Wonderment	"Life is great"
4	Tribal Pride	"We're great (and they're not)"
3	Lone Warrior	"I'm great (and you're not)"
2	Apathetic Victim	"My life sucks"
1	Despairing Hostility	"Life sucks"

(Source: Tribal Leadership)

“Tribal leadership,” argues Logan and his co-authors, “focuses on two things: the words people use and the types of relationships they form.” Moving from Stage to Stage means using different leverage points.

Leverage Points And Success Indicators to Upgrade Tribal Culture

For a person at Stage One:

- Go where the action is.
- Start hanging around people at Stage Two.
- “Cut ties with people who share the “life sucks” language.

The success indicators here are:

- A move away from “life sucks” language to “my life sucks.”
- Passive apathy replaces despairing hostility.
- Cuts ties with people at Stage One.

For a person at Stage Two:

- Start building one-on-one relationships especially with people at Stage Three.
- “In one-on-one sessions, show her how her work makes an impact.”
- Assign short duration projects that require little nagging (as that might reinforce the “my life sucks” language that dominates this Stage.)

The success indicators here are:

- A move away from “my life sucks” to “I’m great.”
- Name-dropping and bragging.
- Lone warrior fighting the good fight.

For a person at Stage Three:

- Encourage them to form three person relationships.
- Encourage them to work on projects bigger than something they could tackle by themselves.
- The way they’ve worked to achieve the success they’ve had up to this point won’t get them where they need to go. Focus on bigger goals and inviting people in to help them.
- Point to role models who use the “we” language and the success they’ve achieved.

The success indicators here are:

- They will use “we” instead of “I.”
- Their network expands from a few dozen to several hundred.
- Working less but getting more done.

For a Person at Stage Four:

- “Stabilize by ensuring (relationships) are based on values, advantages, and opportunity.”
- Encourage opportunistic behaviour to accomplish greatness.

- Recruiting others to the tribe who share values.
- “Perform regular oil changes with the team. In this process, she should lead a discussion about (1) what is working well, (2) what is not working well, and (3) what the team can do to make things that are not working well, work.”

Success indicators here are:

- A switch from “we’re great” to “life is great”
- Networks include a “stunning amount of diversity.”
- Time allocations are based on values and noble missions.
- Exemplar of the tribes values.

Tribal Leadership is a fascinating book that goes on to offer more strategies for leading others (and ourselves) through the stages. For members, we dive into some of the strategies the book offers for growing your network.

94. Charlie Munger on Getting Rich, Wisdom, Focus, Fake Knowledge and More

"In the chronicles of American financial history," writes David Clark in *The Tao of Charlie Munger: A Compilation of Quotes from Berkshire Hathaway's Vice Chairman on Life, Business, and the Pursuit of Wealth*, "Charlie Munger will be seen as the proverbial enigma wrapped in a paradox—he is both a mystery and a contradiction at the same time." On one hand, Munger received an elite education and it shows: He went to Cal Tech to train as a meteorologist for the Second World War and then attended Harvard Law School and eventually opened his own law firm. That part of his success makes sense.

Yet here's a man who never took a single course in economics, business, marketing, finance, psychology, or accounting, and managed to become one of the greatest, most admired, and most honorable businessmen of our age. He was noted by essentially all observers for the originality of his thoughts, especially about business and human behavior. You don't learn that in law school, at Harvard or anywhere else.

Bill Gates said of him: "He is truly the broadest thinker I have ever encountered." His business partner Warren Buffett put it another way: "He comes equipped for rationality... I would say that to try and typecast Charlie in terms of any other human that I can think of, no one would fit. He's got his own mold."

How does such an extreme result happen? How is such an original and unduly capable mind formed? In the case of Munger, it's clearly a combination of unusual genetics and an unusual approach to learning and life.

While we can't have his genetics, we can try to steal his approach to rationality. There's almost no limit to the amount one could learn from studying the Munger mind, so let's at least start with a rundown of some of his best ideas.

Wisdom and Circles of Competence

"Knowing what you don't know is more useful than being brilliant."

"Acknowledging what you don't know is the dawning of wisdom."

Identify your circle of competence and use your knowledge, when possible, to stay away from things you don't understand. There are no points for difficulty at work or in life.

Avoiding stupidity is easier than seeking brilliance.

Of course this principle relates to another of Munger's sayings: "People are trying to be smart—all I am trying to do is not to be idiotic, but it's harder than most people think."

And this reminds me of perhaps my favorite Mungerism of all time, the very quote that sits right beside my desk:

"It is remarkable how much long-term advantage people like us have gotten by trying to be consistently not stupid, instead of trying to be very intelligent."

Divergence

"Mimicking the herd invites regression to the mean."

Here's a simple axiom to live by: If you do what everyone else does, you're going to get the same results that everyone else gets. This means that, taking out luck (good or bad), if you act average, you're going to *be* average. If you want to move away from average, you must diverge. You must be different. And if you want to outperform others, you must be different and correct. As Munger would say, "How could it be otherwise?"

Know When to Fold 'Em

"Life, in part, is like a poker game, wherein you have to learn to quit sometimes when holding a much-loved hand—you must learn to handle mistakes and new facts that change the odds."

Mistakes are an opportunity to grow. How we handle adversity is up to us. This is how we become personally antifragile.

False Models

Echoing Einstein, who said that “Not everything that counts can be counted, and not everything that can be counted counts,” Munger said this about his and Buffett’s shift to acquiring high-quality businesses for Berkshire Hathaway:

“Once we’d gotten over the hurdle of recognizing that a thing could be a bargain based on quantitative measures that would have horrified Graham, we started thinking about better businesses.”

Being Lazy

“Sit on your ass. You’re paying less to brokers, you’re listening to less nonsense, and if it works, the tax system gives you an extra one, two, or three percentage points per annum.”

Time is a friend to a good business and the enemy of the poor business. It’s also the friend of knowledge and the enemy of the new and novel. As Seneca said, “Time discovers truth.”

Investing Is a Perimutuel System

“You’re looking for a mispriced gamble,” says Munger. “That’s what investing is. And you have to know enough to know whether the gamble is mispriced. That’s value investing.” At another time, he added: “You should remember that good ideas are rare— when the odds are greatly in your favor, bet heavily.”

May the odds forever be in your favor. Actually, learning properly is one way you can tilt the odds in your favor.

Focus

When asked about his success, Munger says, “I succeeded because I have a long attention span.”

Long attention spans allow for a deep understanding of subjects. When combined with deliberate practice, focus allows you to increase your skills and get out of your rut. The Art of Focus is a divergent and correct strategy that can help you identify where the leverage points are and apply your efforts toward them.

Fake Knowledge

“Smart people aren’t exempt from professional disasters from overconfidence.”

We’re so used to outsourcing our thinking to others that we’ve forgotten what it’s like to really understand something from all perspectives. We’ve forgotten just how much work that takes. The path of least resistance, however, is just a click away. Fake knowledge, which comes from reading headlines and skimming the news, seems harmless, but it’s not. It makes us overconfident. It’s better to remember a simple trick: anything you’re getting easily through Google or Twitter is likely to be widely known and should not be given undue weight.

However, Munger adds, “If people weren’t wrong so often, we wouldn’t be so rich.”

Sit Quietly

Echoing Pascal, who said some version of “All of humanity’s problems stem from man’s inability to sit quietly in a room alone,” Munger adds an investing twist: “It’s waiting that helps you as an investor, and a lot of people just can’t stand to wait.”

The ability to be alone with your thoughts and turn ideas over and over, without giving in to Do Something syndrome, affects so many of us. A perfectly reasonable option is to hold your ground and await more information.

Deal With Reality

"I think that one should recognize reality even when one doesn't like it; indeed, especially when one doesn't like it."

Munger clearly learned from Joseph Tussman's wisdom. This means facing harsh truths that you might prefer to ignore. It means meeting the world on the world's terms, not according to how you wish it would be. If this causes temporary pain, so be it. "Your pain," writes Kahil Gibran in The Prophet, "is the breaking of the shell that encloses your understanding."

There Is No Free Lunch

We like quick solutions that don't require a lot of effort. We're drawn to the modern equivalent of an old hustler selling an all-curing tonic. However, the world does not work that way. Munger expands:

"There isn't a single formula. You need to know a lot about business and human nature and the numbers... It is unreasonable to expect that there is a magic system that will do it for you."

Acquiring knowledge is hard work. It's reading and adding to your knowledge so it compounds. It's going deep and developing fluency, something Darwin knew well.

Maximization/Minimization

"In business we often find that the winning system goes almost ridiculously far in maximizing and or minimizing one or a few variables—like the discount warehouses of Costco."

When everything is a priority, nothing is a priority. Attempting to maximize competing variables is a recipe for disaster. Picking one variable and relentlessly focusing on it, which is an effective strategy, diverges from the norm. It's hard to compete with businesses that have correctly identified the right variables to maximize or minimize. When you focus on one variable, you'll increase the odds that you're quick and nimble — and can respond to changes in the terrain.

Map and Terrain

"At Berkshire there has never been a master plan. Anyone who wanted to do it, we fired because it takes on a life of its own and doesn't cover new reality. We want people taking into account new information."

Plans are maps that we become attached to. Once we've told everyone there is a plan and what that plan is, especially multi-year plans, we're psychologically more likely to stick to it because coming out and changing it would be admitting we were wrong. This makes it harder for us to change our strategies when we need to, so we're stacking the odds against ourselves. Detailed five-year plans (that will clearly be wrong) are as disastrous as overly general five-year plans (which can never be wrong).

Scrap the plan, isolate the key variables that you need to maximize and minimize, and follow the agile path blazed by Henry Singleton and followed by Buffett and Munger.

The Keys to Good Government

There are three keys: honesty, effectiveness, and efficiency. Munger says:

"In a democracy, everyone takes turns. But if you really want a lot of wisdom, it's better to concentrate decisions and process in one person. It's no accident that Singapore has a much better record, given where it started, than the United States. There, power was concentrated in an enormously talented person, Lee Kuan Yew, who was the Warren Buffett of Singapore."

Lee Kuan Yew put it this way: “With few exceptions, democracy has not brought good government to new developing countries. ... What Asians value may not necessarily be what Americans or Europeans value. Westerners value the freedoms and liberties of the individual. As an Asian of Chinese cultural background, my values are for a government which is honest, effective, and efficient.”

One Step At a Time

“Spend each day trying to be a little wiser than you were when you woke up. Discharge your duties faithfully and well. Slug it out one inch at a time, day by day. At the end of the day—if you live long enough—most people get what they deserve.”

An incremental approach to life reminds one of the nature of compounding. There will always be someone going faster than you, but you can learn from the Darwinian guide to overachieving your natural IQ. In order for this approach to be effective, you need a long axis of time as well as continuous incremental progress.

Getting Rich

“The desire to get rich fast is pretty dangerous.”

Getting rich is a function of being happy with what you have, spending less than you make, and time.

Mental Models

“Know the big ideas in the big disciplines and use them routinely—all of them, not just a few.”

Mental models are the big ideas from multiple disciplines. While most people agree that these are worth knowing, they often think they can identify which models will add the most value, and in so doing they miss something important. There is a reason that the “know-nothing” index fund almost always beats the investors who think they know.

Understanding this idea in greater detail will change a lot of things, including how you read. Acquiring the big ideas — without selectivity — is the way to mimic a know-nothing index fund.

Know-it-alls

“I try to get rid of people who always confidently answer questions about which they don’t have any real knowledge.”

Few things have made as much of a difference in my life as systemically removing (and when that’s not possible, reducing the importance of) people who think they know the answer to everything.

Stoic Resolve

“There’s no way that you can live an adequate life without many mistakes. In fact, one trick in life is to get so you can handle mistakes. Failure to handle psychological denial is a common way for people to go broke.”

While we all make mistakes, it’s how we respond to failure that defines us.

Thinking

“We all are learning, modifying, or destroying ideas all the time. Rapid destruction of your ideas when the time is right is one of the most valuable qualities you can acquire. You must force yourself to consider arguments on the other side.”

“It’s bad to have an opinion you’re proud of if you can’t state the arguments for the other side better than your opponents. This is a great mental discipline.”

Thinking is a lot of work. “My first thought,” William Deresiewicz said in one of my favorite speeches, “is never my best thought. My first thought is always someone else’s; it’s always what I’ve already heard about the subject, always the conventional wisdom.”

Choose Your Associates Wisely

“Oh, it’s just so useful dealing with people you can trust and getting all the others the hell out of your life. It ought to be taught as a catechism. ... [W]ise people want to avoid other people who are just total rat poison, and there are a lot of them.”

No comment needed there.

95. Let Go of Self-Justification

Our desire to justify our actions and believe we've always done the right thing can lead us to distort our view of reality. We prefer preserving our self-image to seeing the truth. Here's how to let go of self-justification.

It can be startling and unsettling to confront how bad humans are at describing reality with any objective accuracy. Because of the way our brains work, how perceptions are distorted, the ambiguity of language, we seem forever destined to never really know this world we are living in. What are we to do?

One answer is to accept that there is no one objective truth so stop searching for it. Instead, we can put our efforts into understanding ourselves a little better, allowing for navigation between the many truths that exist for people, to achieve success.

In Mistakes Were Made (But Not by Me), Carol Tavris and Elliot Aronson explore the role of self-justification in our creation of reality. We make assertions about the world as if they are facts while being completely blind to the subjectivity inherent in knowing anything. Essentially we create a narrative about the world that reflects our beliefs about the kind of person we are and assign to this narrative a 'truth' which does not, in fact, exist.

What is self-justification?

It is not the same thing as lying or making excuses. ... [It] is more powerful and more dangerous than the explicit lie. It allows people to convince themselves that what they did was the best thing they could have done. In fact, come to think of it, it was the right thing.

Self-justification is a portrayal of the brain that, despite its stated goals or desires, is not interested in truth, but rather self-preservation. Admitting you were wrong may save relationships and lives, it may prevent distress and war, but it will also force you to admit that the narrative you have constructed about yourself is wrong. And depending on how committed you are to that narrative, you may be unable to even see that you made a mistake, let alone confront it.

Self-justification has costs and benefits. By itself, it's not necessarily a bad thing. It lets us sleep at night. Without it, we would prolong the awful pangs of embarrassment. We would torture ourselves with regret over the road not taken or over how badly we navigated the road we did take. ... Yet mindless self-justification, like quicksand, can draw us deeper into disaster. It blocks our ability to even see our errors, let alone correct them. It distorts reality, keeping us from getting all the information we need and assessing issues clearly. It prolongs and widens rifts between lovers, friends, and nations. It keeps us from letting go of unhealthy habits. It permits the guilty to avoid taking responsibility for their deeds. And it keeps many professionals from changing outdated attitudes and procedures that can harm the public.

The book contains many unsettling examples from politics and law enforcement. Research based stories of officials who refused to admit their mistakes even when confronted with irrefutable evidence they were wrong. The more invested you are in a situation, the more extensive your narrative, the more likely that narrative has become intertwined with your self-worth and self-esteem, and therefore the harder to rewrite it in light of your errors.

Perhaps the most startling examples of the descent into irreversible self-justification is the research conducted on what the authors call 'the closed loop of clinical judgment'. They discuss the total lack of evidence to support the theory that traumatic events are suppressed by the brain and contrast this with the amount of clinical practitioners who will enter into therapeutic relationships with the pre-supposition that the client's current troubles are being caused by traumatic events that they don't remember.

It becomes a no-win situation for the person seeking therapy – either they spontaneously remember past trauma (which, actually, is the one thing they were not likely to forget in the first place) or they say that they have no memory of being traumatized (in which case the

therapist assumes the memories are still being repressed). Either outcome reinforces the self-justified narrative that the therapist has created.

As evidence accumulated on the fallibility of memory and the many confabulations of recovered-memory cases the promoters of this notion did not admit error; they simply changed their view of the mechanism by which traumatic memories are allegedly lost. It's not repression at work anymore, but dissociation; the mind somehow splits off the traumatic memory and banishes it to the suburbs. This shift allowed them to keep testifying, without batting an eye or ruffling a feather, as scientific experts in cases of recovered memories.

This speaks to investment in the narrative. This is not about admitting that yelling at your spouse about forgetting to buy ice cream was a mistaken over-reaction. In the case of these practitioners, this is their career. It is also the many lives they may have destroyed by unintentionally encouraging false memories of trauma. It would not be easy for any of us to admit mistakes when the consequences of those mistakes are so devastating. How can we remember things that didn't happen? Because self-justification has an effect on our memories.

Between the conscious lie to fool others and unconscious self-justification to fool ourselves, there's a fascinating gray area patrolled by an unreliable, self-serving historian – memory. Memories are often pruned and shaped with an ego-enhancing bias that blurs the edges of past events, softens culpability, and distorts what really happened.

We remember our past in a way that confirms what we believe of ourselves in the present. When we do misremember, our mistakes aren't random. The everyday, dissonance-reducing distortions of memory help us make sense of the world and our place in it, protecting our decisions and beliefs. The distortion is even more powerful when it is motivated by the need to keep our self-concept consistent.

The authors present many fascinating examples of totally fabricated 'memories'. Not ones that are intentional, but situations in which the memories were believed to be genuine and turned out to be false. In all cases the memories had been unconsciously altered or created to support a self-justifying narrative. For example, believing you are an independent free-spirit, you remember your actions as always having been so, or conversely you remember the past as more awful than it was in order to support your narrative of strength and change.

If a memory is a central part of your identity, a self-serving distortion is even more likely." How many of us have come across our old journals or diaries, and felt like they were reading the life story of someone else? We will frequently look at the entries and say 'wow, I don't remember being like this at all'.

Okay, so our memories are unreliable. Hardly a surprise. For the millions of people who frantically search for their car keys every morning, it will not be shocking that your fourth year birthday cake wasn't the bad-ass Batman you remember, but a cute puppy with giant eyes. So why worry about memory?

The self-justifying mechanisms of memory would be just another charming and often exasperating aspect of human nature were it not for the fact that we live our lives, make decisions about people, form guiding philosophies, and construct entire narratives on the basis of memories that are often dead wrong.

When we use our memories to strengthen our narratives, it causes huge dissonance when those memories are revealed to be false. It often requires a rewriting of the entire narrative. This is incredibly hard for humans, provoking what can be thought of as an existential crisis. If I am who I am because of my experiences, what happens when those experiences cease to exist? Do I, in a sense, cease to exist as well?

Admitting Mistakes

In order to be able to admit mistakes, to correct the spiraling self-justification that can have devastating consequences for ourselves and others, we need to accept that "something

we did can be separated from who we are, and who we want to be. Our past selves need not be a blueprint for our future selves. The road to redemption starts with the understanding that who we are includes what we have done but also transcends it, and the vehicle for transcending it is self-compassion.”

This clears the path. It allows us to let go of the past and focus on building the future. More of this would result in an inevitable boon to society.

What is needed is a deep understanding not only of what went wrong then but also of what is going wrong right now, the better to prepare for what could go wrong with current decisions.

The authors argue that is a problem, particularly endemic to North America, that we associate mistakes with failure. We need to shift the thinking, to see mistakes as part of the learning process, necessary steps on the road to making things better.

The amazing thing is, most of us find it refreshing and positive when people admit mistakes. We long to hear our politicians or intellectual leaders or even our relatives say ‘yeah, I messed up. No excuses, I own it, and now I want to fix it’. Hearing this frees us and allows us to do the same.

So try it out. Right now. Think about a mistake you’ve made recently. We all have; with our kids, our partners, our colleagues. Pick one. Think about the narrative you told yourself in the aftermath. Now kick that narrative to the curb and leave it there. You don’t need it anymore. Then find a mirror. Admit to yourself you made a mistake.

Last step. Go find the person you hurt and own up to your mistake. I know this sounds scary, but the more we do this the more authentic and rewarding our relationships will be.

96. Hanlon's Razor: Not Everyone is Out to Get You

Hanlon's Razor teaches us not to assume the worst intention in the actions of others. Understanding Hanlon's Razor helps us see the world in a more positive light, stop negative assumptions, and improve relationships. Let's take a look at some examples.

If you ever feel that the world is against you, you are not alone.

We all have a tendency to assume that when anything goes wrong, the fault lies within some great conspiracy against us. A co-worker fails to give you a report in time? They must be trying to derail your career and beat you to a promotion. Your child drops and breaks an expensive plate? They must be trying to annoy you and waste your time. WiFi in a coffee shop not working? The staff must be lying about having it to lure you in and sample their crappy espresso.

But the simple fact is that these explanations, which we tend to jump to, are rarely true. Maybe your co-worker thought today was Tuesday, not Wednesday. Maybe your child had sticky hands from playing with Play-Doh. Maybe the WiFi router was just broken. This is where Hanlon's razor comes in.

What is Hanlon's Razor?

Hanlon's Razor is a useful mental model which can be best summarized as:

'Never attribute to malice that which can be adequately explained by neglect.'

Like Occam's razor, this heuristic is a useful tool for rapid decision-making and intelligent cognition.

Applying Hanlon's razor in our day-to-day lives allows us to better develop relationships, become less judgmental, and improve rationality. Hanlon's razor allows us to give people the benefit of the doubt and have more empathy. The value of Hanlon's razor is most pronounced in relationships, business matters, and personal happiness.

We all lead complex lives wherein (as Murphy's law states) things are constantly going wrong. When this occurs, a common response is to blame the nearest person and assume they have malicious intent.

People are quick to accuse corporations, politicians, their bosses, employees, coffee shop workers, and even family of trying to derail them. When someone messes up around us, we forget how many times we, too, have done the same. We forget how many times we have elbowed someone in the street, knocked over a drink at a relative's house, or forgotten to meet a friend at the right time. Instead, the perpetrator becomes a source of intense irritation.

To assume intent in such a situation is likely to worsen the problem. None of us can ever know what someone else wants to happen. The smartest people make a lot of mistakes. Inability or neglect is far more likely to be the cause than malice. When a situation causes us to become angry or frustrated, it can be valuable to consider if those emotions are justified. Often, the best way to react to other people causing us problems is by seeking to educate them, not to disdain them. In this way, we can avoid repeats of the same situation.

Origins of Hanlon's Razor

The phrase 'Hanlon's razor' was coined by Robert J. Hanlon, but it has been voiced by many people throughout history, as far back as 1774.

Napoleon Bonaparte famously declared:

'Never ascribe to malice that which is adequately explained by incompetence.'

Goethe wrote similarly in The Sorrows of Young Werther in 1774:

Misunderstandings and neglect create more confusion in this world than trickery and malice. At any rate, the last two are certainly much less frequent.

The German general Kurt von Hammerstein-Equord used Hanlon's razor to assess his men, saying:

I divide my officers into four groups. There are clever, diligent, stupid, and lazy officers. Usually two characteristics are combined. Some are clever and diligent – their place is the General Staff. The next lot are stupid and lazy – they make up 90 percent of every army and are suited to routine duties. Anyone who is both clever and lazy is qualified for the highest leadership duties, because he possesses the intellectual clarity and the composure necessary for difficult decisions. One must beware of anyone who is stupid and diligent – he must not be entrusted with any responsibility because he will always cause only mischief.

The Place of Hanlon's Razor in a Latticework of Knowledge

Hanlon's razor works best when combined and contrasted with other mental models in our latticework of knowledge. Here are some examples of the useful interactions:

- The availability heuristic. This mental model states we misjudge the frequency of recent events. In particular, this occurs if they are vivid and memorable. Many people have a tendency to keep an internal scorecard of other people's mistakes. For example, imagine that a taxi driver takes a wrong turn and makes a journey more expensive. A month later, the same thing occurs with a different driver. We are likely to recall the previous event and react by seeing all taxi drivers as malicious. Instead of accepting both as simple mistakes, the availability of the memory makes us imagine malicious intent. By combining these two mental models, we can understand why certain situations provoke such strong emotions. When memory is vivid and easy to recall, we may ignore Hanlon's razor.
- Confirmation bias. We all have a tendency to look for information that confirms preexisting beliefs. When cognitive dissonance arises, we aim to realign our worldviews. Overcoming confirmation bias is a huge step towards making better choices motivated by logic, not emotions. Hanlon's razor assists with this. If we expect malicious intent, we are likely to attribute it wherever possible. For example, if someone sees a certain politician as corrupt, they will look for information that confirms that. They become unable to identify when mistakes are the result of incompetence or accident.
- Bias from disliking/hating. Hanlon's razor can provide insights when we deal with people, institutions, or entities which we dislike. The more we dislike someone or something, the more likely we are to attribute their actions to malice. When someone we dislike makes a mistake, reacting with empathy and understanding tends to be the last response. Acting in an emotional way is natural, yet immature. It can only worsen the situation. The smartest solution is, no matter how much we dislike someone, to assume neglect or incompetence.
- We also like to attribute our own flaws and failures to someone else, which is a cheap psychological protective mechanism called projection. This allows us to maintain a positive self-image and view friction as someone else's fault rather than our own. It's best to run a reality check before blaming others.

The Uses of Hanlon's Razor

The Media

Modern media treats outrage as a profitable commodity. This often takes the form of articles which often attribute to malice that which could be easily be explained by incompetence or ignorance.

We see examples of this play out in the media multiple times a day. People rush to take offense at anything which contradicts their worldview or which they imagine to do so.

Media outlets are becoming increasingly skilled at generating assumptions of malicious intent. When looking at newspapers, websites, and social media, it can be beneficial to apply Hanlon's razor to what we see.

For example, when Apple's Siri voice search launched, people noticed that it could not search for abortion clinics. This was immediately taken up as proof of misogyny within the company when in fact, a programming error caused the problem.

A similar issue has occurred a number of times with YouTube content policies. When videos discussing LGBTQ matters were filtered on the restrictive viewing mode, many people took extreme offense at this. The reality is that again, this was an algorithm error and not a case of homophobia on the part of their programmers. Countless videos which

do not discuss anything related to LGBTQ issues have also been filtered. This shows it to be a case of confirmation bias, wherein people see the malice they expect to see.

Communication and Relationships

One of the most valuable uses of Hanlon's razor is in relationships and communication. It is common for people to damage relationships by believing other people are intentionally trying to cause problems for them, or behaving in a way intended to be annoying. In most cases, these situations are the result of inability or accidental mistakes.

Douglas Hubbard expanded upon the idea in Failure of Risk Management: Why it's Broken and How to Fix it:

I would add a clumsier but more accurate corollary to this: 'Never attribute to malice or stupidity that which can be explained by moderately rational individuals following incentives in a complex system of interactions.' People behaving with no central coordination and acting in their own best interest can still create results that appear to some to be clear proof of conspiracy or a plague of ignorance.

A further example can be seen when semantic barriers interfere with communication. We have all encountered people struggling to speak our native language, perhaps because they are a tourist or have recently moved to the country. You have probably seen someone gets frustrated at them or even been the one getting annoyed. Or if you have ever traveled to or lived in a country where you are not fluent in the language, you might have been the one people got annoyed at. Realistically, the person asking you for directions or struggling to order their coffee is not mixing up their nouns and speaking in a strong accent on purpose.

Hanlon's razor tells us they are merely inarticulate and are not trying to waste anyone's time. The same issues occur when a person uses language which is considered too complex or too basic. This may form a semantic barrier, as other people assume they are trying to confuse them or are being blunt.

A shortcut to regulating what can be strong reactions to inadvertent events is to conscientiously reframe the perpetrator as a toddler knocking over a vase. Their actions are rendered unintentional and clumsy, highlighting their need for help, maturation or supervision, allowing you to rapidly regain composure and not take it personally.

Exceptions and Issues

Like any mental model, Hanlon's razor has its limitations and its validity has been contested. Some critics consider Hanlon's razor to be an overly naive idea that can blind people to true malice. While people have malicious intent far less often than we think, it is still something that must be taken into account. Sometimes actions which could be attributed to incompetence are in fact consciously or unconsciously malicious.

An instance of Hanlon's razor being proven wrong is the mafia. Prior to the 1960s, the existence of the mafia was considered to be a conspiracy theory. Only when a member contacted law enforcement did police realize that the malice being perpetrated was carefully orchestrated.

To make the best use of Hanlon's razor, we must be sure to put it in context, taking into account logic, experience, and empirical evidence. Make it a part of your latticework of mental models, but do not be blind to behavior that is intended to be harmful.

97. Emergence and Power — Four 13th-Century Sisters Who Became Queens

"[S]ome systems ... are very sensitive to their starting conditions, so that a tiny difference in the initial push you give them causes a big difference in where they end up, and there is feedback, so that what a system does affects its own behavior."

— John Gribbin, *Deep Simplicity*

Emergence is the occurrence of genuinely new and novel qualities that are unique to a system and thus separate from its components.

Emergence can be a tricky concept, but it is an extremely useful model to explore. It allows us to understand why some things are greater than the sum of their parts. It demonstrates that power can arise from components that on their own are relatively powerless.

A school of fish is a perfect example. If you studied the movement of one fish, you would have no appreciation for the shape and behavior that 10,000 of them together will produce. Essentially, the complex behavior they exhibit as a group is more than the physical motion of each individual fish.

Understanding that organisms, including humans, can self-organize into systems that have properties that are unique to the collective is a lens through which you can better understand the behaviors of large organizations such as a bureaucracy, political system, or a marketplace.

Western Europe in the 13th century was almost dysfunctional. The borders of England, France, and Germany were not what we'd recognize today, and most rulers spent their time (and money) constantly reorganizing the geopolitical boundaries. Peace treaties were seasonal and monarchs would go into enormous debt to finance various exploits designed to take, or take back, land. Taxes were a certainty. Not so much who you'd be paying them to.

Women of the royalty and nobility were a huge component of these 'raising funds for invasion' schemes. Maybe beauty mattered, and there is some evidence that Kings and Queens did occasionally love each other. But money mattered more. High-class women came with dowries of lands and goods, which helped fund the ongoing conquests. So women didn't get to choose whom they were going to marry. It was like Monopoly trading – I'll give you Pacific Avenue for St. Charles and Ventnor and free rent for the next five rolls.

In 1230 four sisters lived in Provence, then part of the Holy Roman Empire (now part of France). Their father was a Count, which made them nobility, but not royalty. They didn't have loads of money, but they were pretty. They had good marriage prospects, but not amazing ones. They should not have all ended up as Queens. And yet, that's what happened.

Nancy Goldstone, in her book Four Queens, explains the geopolitical maneuverings that brought about this extraordinary set of circumstances.

Marguerite, the eldest, was the first to marry. She was chosen by the Dowager Queen of France, Blanche de Castile, for her eldest son Louis IX. Provence's neighbor Toulouse was acting up, violating his treaty with France and the Dowager wanted friends in the region. A storm was brewing with England, and she knew France couldn't handle a war on two fronts. So Marguerite, pretty, but of inferior rank, was chosen, as long as her family could provide a dowry of 10000 silver marks (needed for, among other things, dealing with the English). They couldn't, so they pledged some Provence real estate which was good enough for all parties and the deal was done.

Eleanor was next, the second eldest of the sisters. She married Henry III, the King of England. Eleanor was even a less obvious choice than Marguerite. Henry III was broke,

and what little liquid assets the Provence family had all went to Marguerite's marriage. Goldstone argues that it is the first marriage that made all the difference for the second. Marguerite's marriage to the King of France had elevated the position of all the sisters. Plus, Henry was sick of losing to France and so sought Eleanor out. If Blanche "had selected a daughter of the count of Provence to be the wife of her eldest son [which] carried weight with Henry. ... There must be something to it." Essentially the King of England wanted what the King of France had.

The third daughter, Sanchia, was the unfortunate victim of her older sisters' success. Also unhelpful was that she was rumored to be the most beautiful of the four. She was propositioned by Henry's brother, Richard, the Earl of Cornwall and the richest man in England. They married, and Goldstone shows how her family connections helped him eventually buy the title of King of Germany, then part of the Holy Roman Empire (allegiances changed before Richard could be crowned Emperor.)

Finally, there was Beatrice. Because he had no sons, the father of the four sisters chose his estate, the rule of Provence, to be passed down to his youngest daughter Beatrice upon his death. When he died, she was still single and therefore had the best dowry to offer. Perhaps due to a dearth of available kings, she married the King of France's youngest brother, Charles. Goldstone notes that they were well matched in terms of ambition. Their political and military endeavors eventually gave them the title of King and Queen of Sicily.

The key concept of emergence that is at play here is that components of a system self-organize to produce a state of affairs that is neither obvious nor predictable if you focus on the capabilities of the components themselves. The coming together produces capabilities that are new.

The internet encyclopedia of philosophy explains it this way:

Effects are resultant if they can be calculated by the mere addition or subtraction of causes operating together, as with the weight of an object, when one can calculate its weight merely by adding the weights of the parts that make it up. Effects are emergent if they cannot be thus calculated because they are qualitatively novel compared to the causes from which they emerge.

The power that each sister wielded in each marriage, if we generally consider how much power an individual woman would have had in a royal relationship, does not add up to explain their immense influence over the events of the mid-13th century.

Goldstone writes that "almost nothing of significance that occurred in western Europe during the period in which they lived was not influenced by the actions of this family. It is impossible to fully understand the underlying political motivations of the thirteenth century without them."

The thing about emergent phenomenon is you can't point to the components and say, 'oh yeah, it's because of this and that'. Like the school of fish, you can't say, 'they're moving this way because of fish number 8 and number 63'. You can only look at the behavior of the school as a whole. And this whole has, for example, a power to evade predators that the individual doesn't have.

So too with the sisters from Provence. Looking at the influence Marguerite developed over her husband or the fact that Eleanor and Henry ended up respecting each and thus worked as a team is not enough to explain what they could achieve. It wasn't Sanchia alone who got Richard a crown, and Beatrice's money didn't directly buy Sicily. The sisters were, in varying degrees, determined, smart, pious, ambitious, and beautiful. And they all had sons. But although these things may have played a part, you can't point to any of them and say it was the deciding factor in the influence they had. The reach of the collective was more than adding up the reach of each individual. A higher degree of power emerged, and one that couldn't have been predicted.

Goldstone tells of the reaction of the family when one of the Queens' uncles was captured in battle. "The news of his capture spread quickly to the courts of Europe and the family took immediate action. In England, Henry and Eleanor shut down trade with northern Italy, and forcibly detained all merchants and citizens from Asti and Turin who happened to be visiting at the time. In France, Marguerite had Louis follow suit, an action that resulted in hundreds of arrests. She then demanded a payment of ten thousand pounds, in addition to the release of her relative, as a condition of freedom. Beatrice of Savoy, the sisters' mother (in a bit of a power struggle with her youngest daughter over lands in Provence), ordered her soldiers to close the roads between Switzerland and Provence and took numerous prisoners. Sanchia even persuaded Richard to do his part by forwarding the money needed to underwrite a rescue attempt. Faced with the poverty brought on by the imposition of what were, in effect, international economic sanctions, the citizens of Asti realized their mistake, and let Uncle Thomas go."

If Marguerite was the only one of the sisters who was a Queen, would the King of England and his brother have actively participated in the rescue of an ally of the King of France? Likely not, given the history between the two countries, which, both before and after, was characterized more by war than cooperation.

The sisters didn't always work together, but this supports the explanation of emergence, which occurs due to interconnectivity and complex causal relations, not from any organized, external control factor. The power the sisters had was not conscientiously developed and wielded, it was more a force that influenced behavior and outcomes for an entire continent for over 30 years.

98. Cleopatra and Self-Preservation

*“For the last time in two thousand years Cleopatra VII stands offstage.
In a matter of days she will launch herself into history,
which is to say that faced with the inevitable,
she will counter with the improbable. It is 48 BC.”*

— Stacy Schiff

Cleopatra (69BC 30-BC) was a master of self-preservation. She lived a life under constant threat and yet never fell victim to it. Her success was so uncommon, particularly for a woman, that it seems like history has been trying to make excuses for it for over 2000 years. But as Stacy Schiff illuminates in her book, Cleopatra: A Life, her story is worth learning and taking inspiration from. Cleopatra has a lot to teach us about drawing on all our resources in the face of adversity.

Self-preservation in the biological sense is about our very profound instinct to keep ourselves alive. This instinct is exhibited by all animals and is about the survival of our genes. It's not about spirituality or morality or about how we feel. It's a biological desire to live until we can pass our genes onto the next generation and ensure their survival.

As John Medina explains in Brain Rules, “Without a flexible, immediately available, highly regulated stress response, we would die. Remember, the brain is the world's most sophisticated survival organ. All of its many complexities are built toward a mildly erotic, singularly selfish goal: to live long enough to thrust our genes on to the next generation. Our reactions to stress serve the live-long-enough part of that goal. Stress helps us manage the threats that could keep us from procreating.”

This sophisticated stress response is an extremely useful system to have. It works when it needs to — no effort required — propelling us to fight, flight, or freeze. It allows us to process information so quickly that we are not conscious of the thoughts. We obey our bodies when it tells us not to move a muscle, to attack with as much violence as possible, or to run like hell.

But it has to be able to turn off. It can't be the only system you use every day. Why? Because it is meant to come out only in situations where our life is threatened.

Our stress responses were shaped to solve problems that lasted not for years, but for seconds. ... These days, our stresses are measured not in moments with mountain lions, but in hours, days, and sometimes months with hectic workplaces, screaming toddlers, and money problems. Our system isn't built for that. And when moderate amounts of hormone build up to large amounts, or when moderate amounts of hormone hang around too long, they become quite harmful.

And so, in human society, which often seems one long, ongoing battle, we can't exist in a constant state of fight/flight/freeze if we are to preserve both our genes and our sanity. We need to integrate other capabilities of our brain into our dealings with stress, such as rational, strategic thought that leverages the resources of knowledge we've built over the years. And this is where Cleopatra excelled.

To be fair, we all don't respond the same way to stress. As Medina says, “Psychiatrists long have observed that some people are more tolerant of stress than others. ... Some people's genetic complement naturally buffers them against the effects of stress, even the chronic type.”

We will never know if this is true for Cleopatra, but there is no doubt she rose to the formidable challenges of being Queen of Egypt circa 40 BCE. She adapted, survived, and thrived despite constant peril. So maybe her story can illuminate for us a different mindset with which to deal with our daily stressors.

First she had to deal with a tradition of murder within her own family.

Schiff explains in Cleopatra: A Life:

Over the generations the family indulged in what has been termed ‘an orgy of pillage and murder’ ... Over and over mothers sent troops against sons. Sisters waged war against brothers. Cleopatra’s great-grandmother fought one civil war against her parents, a second against her children.

Because, in Cleopatra’s Ptolemy line, brothers often married sisters, all children had legitimate claims to the throne and often ended up disposing of each other. In keeping up with family practices, Cleopatra got rid of a brother/husband and a sister who had designs on her throne.

So right from the beginning it was kill or be killed. There were no allies in the home. When Caesar arrived in 48 BCE, Cleopatra’s brother was occupying the throne having banished her to the desert.

That summer she rallied a band of mercenaries, at a desert camp, under the glassy heat of the Syrian sun. She was twenty-one, an orphan and an exile. Already she had known both excessive good fortune and its flamboyant consort, calamity. Accustomed to the greatest luxury of the day, she held court two hundred miles from the ebony doors and onyx floors of home. Her tent amid the scrub of the desert was the closest she had come in a year. Over those months she had scrambled for her life, fleeing through Middle Egypt, Palestine, and southern Syria. She had spent a dusty summer raising an army.

She was resourceful. She took the throne back and held on for 18 tumultuous years.

Politics in the Mediterranean during her time were volatile. Changing allegiances, murder, competing personalities and ideologies characterized the Roman spirit. Caesar had formed a vision of how powerful Rome could be, and this was tempting to many.

Egypt was the richest country on the Mediterranean. Because it had the most fertile soil, it could grow and produce exceptional amounts of food. So it was an early stop in any attempts to conquer the world, because it could fund the efforts.

Rather than focus on the things she couldn’t overtly control (e.g. the timing of Roman invasions), she set to order those elements within her sphere of power and influence. The Greek language, “by Cleopatra’s day [was] the language of business and bureaucracy ... While Egyptian speakers learned Greek, it was rare that anyone ventured in the opposite direction. To the punishing study of Egyptian, however, Cleopatra applied herself. She was allegedly the first and only Ptolemy to bother to learn the language of the 7 million people over whom she ruled.”

She worked hard to gain and maintain the support of her people because no monarch wants to be fighting on two fronts at once. She got rid of her competitors, spent money on developing Egypt’s infrastructure, and as Schiff explains, learned Egyptian culture so well that she was able to invoke their Goddess Isis as “provider of wisdom and of material and spiritual sustenance.” Rome was always going to be a problem, but she did an excellent job keeping peace on the home front. She had the longest reign of all the Ptolemies.

When the inevitable Roman intrusions came she aimed to best support Egyptian interests, sometimes backing the wrong horse. After Caesar, there was a fight for Roman leadership.

When the dust settled Mark Antony was in charge of everything East of Rome and Cleopatra was in the awkward and potentially fatal position of not having supported him.

Confident though she may have been, contemptuous though she may have appeared, Cleopatra left nothing in her preparation to chance. ... She would have known she was entering a sort-of sweepstakes for Antony’s attention. She seemed determined to conjure a display so stunning it would propel Plutarch to Shakespearean heights, as it would elicit from Shakespeare his richest poetry. And she succeeded. In the annals of indelible entrances – the wooden horse into Troy; Christ into Jerusalem; Benjamin Franklin into Philadelphia; the Beatles on Ed Sullivan’s stage – Cleopatra’s alone lifts off the page in iridescent color, amid inexhaustible, expensive clouds of incense, a sensational, simultaneous assault on every sense.

She was also extremely adept at framing her actions to suit whatever narrative she needed to preserve her power. By the time she was dealing with Mark Antony, “her ability to molt, instantly and as the situation required, to slide effortlessly from one idiom to another, her irresistible charm, were already well established.”

Cleopatra worked her whole life to keep her independence from Rome, to maintain her control over the land of which she was Queen. She fought to preserve her power and in doing so preserve her self and give her children the best chance of survival. “Cleopatra could generally be counted on to do the intelligent thing,” Schiff writes. “She was fighting for her life, her throne, and her children. She had ruled for two decades, and was without illusion.”

She adapted to the many vicissitudes of life by learning as much as she could, making sure her risks were calculated, and never giving up control of the position she held. Even her death was on her own terms. Although Schiff artfully argues that the actual circumstances of her death are unlikely to ever be known for sure, “for any number of reasons Cleopatra was unlikely to have recruited an asp, or an Egyptian cobra, for the job. A woman known for her crisp decisions and meticulous planning would surely have hesitated to entrust her fate to a wild animal.”

Eventually, Cleopatra could not outrun the aggression of Rome in pursuing the fertile Nile valley. But her intelligence and adaptability allowed her to last a remarkably long time in the face of a lifetime of tumult.

99. Confirmation Bias And the Power of Disconfirming Evidence

Confirmation bias is our tendency to cherry-pick information that confirms our existing beliefs or ideas. Confirmation bias explains why two people with opposing views on a topic can see the same evidence and come away feeling validated by it. This cognitive bias is most pronounced in the case of ingrained, ideological, or emotionally charged views. Failing to interpret information in an unbiased way can lead to serious misjudgments. By understanding this, we can learn to identify it in ourselves and others. We can be cautious of data that seems to immediately support our views.

When we feel as if others “cannot see sense,” a grasp of how confirmation bias works can enable us to understand why. Willard V. Quine and J.S. Ullian described this bias in *The Web of Belief* as such:

The desire to be right and the desire to have been right are two desires, and the sooner we separate them the better off we are. The desire to be right is the thirst for truth. On all counts, both practical and theoretical, there is nothing but good to be said for it. The desire to have been right, on the other hand, is the pride that goeth before a fall. It stands in the way of our seeing we were wrong, and thus blocks the progress of our knowledge.

Experimentation beginning in the 1960s revealed our tendency to confirm existing beliefs, rather than questioning them or seeking new ones. Other research has revealed our single-minded need to enforce ideas.

“What the human being is best at doing is interpreting all new information so that their prior conclusions remain intact.”

— Warren Buffett

Like many mental models, confirmation bias was first identified by the ancient Greeks. In *The History of the Peloponnesian War*, Thucydides described this tendency as such:

For it is a habit of humanity to entrust to careless hope what they long for, and to use sovereign reason to thrust aside what they do not fancy.

Our use of this cognitive shortcut is understandable. Evaluating evidence (especially when it is complicated or unclear) requires a great deal of mental energy. Our brains prefer to take shortcuts. This saves the time needed to make decisions, especially when we’re under pressure. As many evolutionary scientists have pointed out, our minds are

unequipped to handle the modern world. For most of human history, people experienced very little new information during their lifetimes. Decisions tended to be survival based. Now, we are constantly receiving new information and have to make numerous complex choices each day. To stave off overwhelm, we have a natural tendency to take shortcuts. In “The Case for Motivated Reasoning,” Ziva Kunda wrote, “we give special weight to information that allows us to come to the conclusion we want to reach.” Accepting information that confirms our beliefs is easy and requires little mental energy. Contradicting information causes us to shy away, grasping for a reason to discard it.

In *The Little Book of Stupidity*, Sia Mohajer wrote:

The confirmation bias is so fundamental to your development and your reality that you might not even realize it is happening. We look for evidence that supports our beliefs and opinions about the world but excludes those that run contrary to our own... In an attempt to simplify the world and make it conform to our expectations, we have been blessed with the gift of cognitive biases.

“The human understanding when it has once adopted an opinion, draws all things else to support and agree with it. And though there be a greater number and weight of instances to be found on the other side, yet these it either neglects and despises, or else by some distinction sets aside and rejects.”

— Francis Bacon

How Confirmation Bias Clouds Our Judgment

The complexity of confirmation bias arises partly from the fact that it is impossible to overcome it without an awareness of the concept. Even when shown evidence to contradict a biased view, we may still interpret it in a manner that reinforces our current perspective.

In one Stanford study, half of the participants were in favor of capital punishment, and the other half were opposed to it. Both groups read details of the same two fictional studies. Half of the participants were told that one study supported the deterrent effect of capital punishment, and the other opposed it. The other participants read the opposite information. No matter, the majority of participants stuck to their original views, pointing to the data that supported it and discarding that which did not.

Confirmation bias clouds our judgment. It gives us a skewed view of information, even when it consists only of numerical figures. Understanding this cannot fail to transform a person’s worldview — or rather, our perspective on it. Lewis Carroll stated, “we are what we believe we are,” but it seems that the world is also what we believe it to be.

A poem by Shannon L. Alder illustrates this concept:

Read it with sorrow and you will feel hate.

Read it with anger and you will feel vengeful.

Read it with paranoia and you will feel confusion.

Read it with empathy and you will feel compassion.

Read it with love and you will feel flattery.

Read it with hope and you will feel positive.

Read it with humor and you will feel joy.

Read it without bias and you will feel peace.

Do not read it at all and you will not feel a thing.

Confirmation bias is somewhat linked to our memories (similar to availability bias). We have a penchant for recalling evidence that backs up our beliefs. However neutral the original information was, we fall prey to selective recall. As Leo Tolstoy wrote:

The most difficult subjects can be explained to the most slow-witted man if he has not formed any idea of them already; but the simplest thing cannot be made clear to the most

intelligent man if he is firmly persuaded that he knows already, without a shadow of doubt, what is laid before him.

“Beliefs can survive potent logical or empirical challenges. They can survive and even be bolstered by evidence that most uncommitted observers would agree logically demands some weakening of such beliefs. They can even survive the destruction of their original evidential bases.”

— Lee Ross and Craig Anderson

Why We Ignore Contradicting Evidence

Why is it that we struggle to even acknowledge information that contradicts our views?

When first learning about the existence of confirmation bias, many people deny that they are affected. After all, most of us see ourselves as intelligent, rational people. So, how can our beliefs persevere even in the face of clear empirical evidence? Even when something is proven untrue, many entirely sane people continue to find ways to mitigate the subsequent cognitive dissonance.

Much of this is the result of our need for cognitive consistency. We are bombarded by information. It comes from other people, the media, our experience, and various other sources. Our minds must find means of encoding, storing, and retrieving the data we are exposed to. One way we do this is by developing cognitive shortcuts and models. These can be either useful or unhelpful.

Confirmation bias is one of the less-helpful heuristics which exists as a result. The information that we interpret is influenced by existing beliefs, meaning we are more likely to recall it. As a consequence, we tend to see more evidence that enforces our worldview. Confirmatory data is taken seriously, while disconfirming data is treated with skepticism. Our general assimilation of information is subject to deep bias.

Constantly evaluating our worldview is exhausting, so we prefer to strengthen it instead. Plus holding different ideas in our head is hard work. It's much easier to just focus on one. We ignore contradictory evidence because it is so unpalatable for our brains. According to research by Jennifer Lerner and Philip Tetlock, we are motivated to think critically only when held accountable by others. If we are expected to justify our beliefs, feelings, and behaviors to others, we are less likely to be biased towards confirmatory evidence. This is less out of a desire to be accurate, and more the result of wanting to avoid negative consequences or derision for being illogical. Ignoring evidence can be beneficial, such as when we side with the beliefs of others to avoid social alienation.

Examples of Confirmation Bias in Action

Creationists vs. Evolutionary Biologists

A prime example of confirmation bias can be seen in the clashes between creationists and evolutionary biologists. The latter use scientific evidence and experimentation to reveal the process of biological evolution over millions of years. The former see the Bible as being true in the literal sense and think the world is only a few thousand years old. Creationists are skilled at mitigating the cognitive dissonance caused by factual evidence that disproves their ideas. Many consider the non-empirical “evidence” for their beliefs (such as spiritual experiences and the existence of scripture) to be of greater value than the empirical evidence for evolution.

Evolutionary biologists have used fossil records to prove that the process of evolution has occurred over millions of years. Meanwhile, some creationists view the same fossils as planted by a god to test our beliefs. Others claim that fossils are proof of the global flood described in the Bible. They ignore evidence to contradict these conspiratorial ideas and instead use it to confirm what they already think.

Doomsayers

Take a walk through London on a busy day, and you are pretty much guaranteed to see a

doomsayer on a street corner, ranting about the upcoming apocalypse. Return a while later and you will find them still there, announcing that the end has been postponed.

In *When Prophecy Fails*, Leon Festinger explained the phenomenon this way:

Suppose an individual believes something with his whole heart; suppose further that he has a commitment to this belief, that he has taken irrevocable actions because of it; finally, suppose that he is presented with evidence, unequivocal and undeniable evidence, that his belief is wrong: what will happen? The individual will frequently emerge, not only unshaken but even more convinced of the truth of his beliefs than ever before. Indeed, he may even show a new fervor about convincing and converting people to his view.

Music

Confirmation bias in music is interesting because it is actually part of why we enjoy it so much. According to Daniel Levitin, author of *This Is Your Brain on Music*:

As music unfolds, the brain constantly updates its estimates of when new beats will occur, and takes satisfaction in matching a mental beat with a real-in-the-world one.

Witness the way a group of teenagers will act when someone puts on “Wonderwall” by Oasis or “Creep” by Radiohead. Or how their parents react to “Starman” by Bowie or “Alone” by Heart. Or even their grandparents to “The Way You Look Tonight” by Sinatra or “Non, Je ne Regrette Rien” by Edith Piaf. The ability to predict each successive beat or syllable is intrinsically pleasurable. This is a case of confirmation bias serving us well. We learn to understand musical patterns and conventions, enjoying seeing them play out.

Homeopathy

The multibillion-dollar homeopathy industry is an example of mass confirmation bias.

Homeopathy was invented by Jacques Benveniste, a French researcher studying histamines. Benveniste became convinced that as a solution of histamines was diluted, the effectiveness increased due to what he termed “water memories.” Test results were performed without blinding, leading to a placebo effect.

Benveniste was so certain of his hypothesis that he found data to confirm it and ignored that which did not. Other researchers repeated his experiments with appropriate blinding and proved Benveniste’s results to have been false. Many of the people who worked with him withdrew from science as a result.

Yet homeopathy supporters have only grown in numbers. Supporters cling to any evidence to support homeopathy while ignoring that which does not.

“One of the biggest problems with the world today is that we have large groups of people who will accept whatever they hear on the grapevine, just because it suits their worldview—not because it is actually true or because they have evidence to support it. The striking thing is that it would not take much effort to establish validity in most of these cases... but people prefer reassurance to research.”

— Neil deGrasse Tyson

Scientific Experiments

In good scientific experiments, researchers should seek to falsify their hypotheses, not to confirm them. Unfortunately, this is not always the case (as shown by homeopathy). There are many cases of scientists interpreting data in a biased manner, or repeating experiments until they achieve the desired result. Confirmation bias also comes into play when scientists peer-review studies. They tend to give positive reviews of studies that confirm their views and of studies accepted by the scientific community.

This is problematic. Inadequate research programs can continue past the point where the evidence points to a false hypothesis. Confirmation bias wastes a huge amount of time and funding. We must not take science at face value and must be aware of the role of biased reporting.

“The eye sees only what the mind is prepared to comprehend.”

— Robertson Davies

Conclusion

This article can provide an opportunity for you to assess how confirmation bias affects you. Consider looking back over the previous paragraphs and asking:

- Which parts did I automatically agree with?
- Which parts did I ignore or skim over without realizing?
- How did I react to the points which I agreed or disagreed with?
- Did this post confirm any ideas I already had? Why?
- What if I thought the opposite of those ideas?

Being cognizant of confirmation is not easy, but with practice, it is possible to recognize the role it plays in the way we interpret information. You need to search out disconfirming evidence.

As Rebecca Goldstein wrote in *Incompleteness: The Proof and Paradox of Kurt Godel*: *All truths — even those that had seemed so certain as to be immune to the very possibility of revision — are essentially manufactured. Indeed, the very notion of the objectively true is a socially constructed myth. Our knowing minds are not embedded in truth. Rather, the entire notion of truth is embedded in our minds, which are themselves the unwitting lackeys of organizational forms of influence.*

100. Galilean Relativity and the Invasion of Scotland

A few centuries ago, when Galileo (1564-1642) was trying to make a couple of points about how our world really works, one of the arguments that frequently came up in response to his 'the earth orbits the sun' theory was "if the earth is moving through space, how come I don't notice?"

Not that I have much to begin with, but I don't feel the wind constantly in my hair, I don't get orbit-induced motion sickness, so why, Galileo, don't I notice this movement as the earth is spinning around over 100,000 km per hour?

His answer is known as Galilean Relativity and it contains principles that have broad application in life.

Understanding Galilean Relativity allows you to consider your perspective in relation to results. Are you really achieving what you think you are?

First, an explanation of the theory.

Imagine you are on a ship that has reached constant velocity (meaning without a change in speed or direction). You are below decks and there are no portholes. You drop a ball from your raised hand to the floor. To you, it looks as if the ball is dropping straight down, thereby confirming gravity is at work. You are able to perceive this vertical shift as the ball changed its location by about three feet.

Now imagine you are a fish (with special x-ray vision) and you are watching this ship go past. You see the scientist inside, dropping a ball. You register the vertical change in the position of the ball. But you are also able to see a horizontal change. As the ball was pulled down by gravity it also shifted its position east by about 20 feet. The ship moved through the water and therefore so did the ball. The scientist on board, with no external point of reference, was not able to perceive this horizontal shift.

This analogy helped Galileo explain why we don't notice the earth moving — because we're at the same constant velocity, moving with our planet.

It can also show us the limits of our perception. And how we must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we've got all the information, if we're on the ship, the fish in the ocean has more he can share.

History offers an illuminating example of this principle at work.

In the early fourteenth century, two English kings (Edwards I and II) were repeatedly in conflict with Scotland over Scottish independence.

Nationalism wasn't as prevalent as an identity characteristic as it is today. Lands came and went with war, marriage, and papal edicts, and the royal echelons of Europe spent a lot of time trying to acquire and hold on to land, as that is where their money ultimately came from.

There were a lot of factors that led Edward I, King of England, to decide that Scotland should be his. It has to do with how William the Conqueror divided things up in the area in 1066, the constant struggle by the English for the strategic upper hand against France, and more generally, the fact that the King of England was at the head of a feudal system that, "by enlarging a class of professional soldiers who owed military service in payment for land, it enabled it," says William Rosen in his book [The Third Horseman: Climate Change and the Great Famine of the 14th Century](#).

Edward I wanted to rule Scotland. The Scots weren't interested. He invaded half a dozen times and succeeded only in giving birth to a separate Scottish identity. His desire for Scotland became his Galilean ship. He couldn't see beyond that desire to understand how his actions were actually fundamentally undermining his goals.

History regards Edward I as a decent king. Strategic in battle, a good administrator, and so one can assume that what he generally wanted was to rule over a prosperous and powerful country. In his mind then it may have been a very simple equation — since

prosperity in the middle ages was tied up with land, then to have more of it must be good. And Scotland was in a convenient location, as opposed to, say, Mongolia.

What Edward I did not see was that the repeated invasion of Scotland was undermining the very prosperity and power he was hoping to augment. It was costing tons of money, money that had to be raised from the nobility that supported his monarchy, which in turn had to be raised via the peasants from the land. People were getting sick of watching their taxes go up in flames on the Scottish border. And, as Rosen claims, "A king's authority depends utterly on the loyalty and faith of his people." Lose your popular support and you lose everything.

When Edward I died, his son, Edward II, inherited his father's quest to own Scotland. He too repeatedly invaded with no lasting success. And he had it even worse. The beginning of his reign coincided with a major famine that decimated the population. This was followed by diseases that swept through the agricultural animal populations. So there was less money to support war.

But Edward II kept taxing and invading Scotland anyway, indifferent to the plight of his people. This contributed to widespread disgust with his reign and eventually led to his being disposed of, and likely murdered, in favor of his son. A cautionary tale on what happens when you lose the loyalty of the people you are meant to be leading!

This all begs the question, was Scotland really such a great prize to justify the repeated attempts to conquer it?

The answer is no. As Rosen writes, "the conquest of medieval Scotland was, by any rational economic calculus, a poor bargain for both of England's King Edwards, who together spent more than the entire value of the country in one failed expedition after another."

They certainly did not see this.

It is important to know that in Galilean relativity, neither the perspective of the scientist on the ship nor the fish in the ocean is incorrect. Both perspectives are true for those doing the observing. Because the scientist has no external frame of reference, he is not mistaken when he says that the ball moved only vertically, and not horizontally.

You aren't always going to be able to adjust for Galilean relativity. Given the roles, expectations, and mythology surrounding kings, both Edwards were acting according to the viewpoint they had.

So discussing the attempted conquest of Scotland by both Kings is not about revealing that their assumptions were incorrect. From their perspective acquiring land was always a good thing. But by failing to consider other perspectives they didn't achieve their intended results – control of Scotland – and, more importantly, were unable to appreciate the results they were affecting. More land cannot come at the expense of support for your leadership.

It is likely that at least one advisor might have said to the Edwards, 'hey, maybe you should spend some more money on preventing the starvation of the population that pays you taxes and take a break on this Scottish thing'. This is where understanding Galilean relativity is useful – you won't shoot the messenger.

You will know that sometimes you are on the ship, and the limitations this entails, and so be open when the fish shares his perspective with you.

101. Understanding the Limitations of Maps

Maps are flawed but useful. For instance, we can leverage the experiences of others to help us navigate through territories that are, to us, new and unknown. We just have to understand and respect the inherent limitations of maps whose territories may have changed. We have to put some work into really seeing what the maps can show us. Here are three things you need to think about when using a map: The perspective, the author, and the territory.

The Perspective

Maps are an abstraction, which means information is lost in order to save space. So perhaps the most important thing we can do before reading a map is to stop and consider what choices have been made in the representation before us.

First, there are some limitations based on the medium used, like paper or digital, and the scale of the territory you are trying to represent. Take the solar system. Our maps of the solar system typically fit on one page. This makes them useful for understanding the order of the planets from the sun but does not even come close to conveying the size of the territory of space.

Bill Bryson explains in A Short History of Nearly Everything, “such are the distances, in fact, that it isn’t possible, in any practical terms, to draw the solar system to scale. ... On a diagram of the solar system to scale, with the Earth reduced to about the diameter of a pea, Jupiter would be over a thousand feet away, and Pluto would be a mile and half distant (and about the size of a bacterium, so you wouldn’t be able to see it anyway).”

Maps are furthermore a single visual perspective chosen because you believe it the best one for what you are trying to communicate. This perspective is both literal — what I actually see from my eyes, and figurative — the bias that guides the choices I make.

It’s easy to understand how unique my perspective is. Someone standing three feet away from me is going to have a different perspective than I do. I’ve been totally amazed by the view out of my neighbour’s window.

Jerry Brotton, in his book A History of the World in Twelve Maps, reveals that “the problem of defining where the viewer stands in the relation to a map of the world is one geographers have struggled with for centuries.” Right from the beginning, your starting point becomes your frame of reference, the centre of understanding that everything else links back to.

In an example that should be a classic, but isn’t because of a legacy of visual representation that has yet to change, most of us seriously underestimate the size of Africa. Why? Because, as Tim Marshall explains in his book Prisoners of Geography, most of us use the standard Mercator world map, and “this, as do other maps, depicts a sphere on a flat surface and thus distorts shapes.” A world map always has to be distorted, with a bent toward the view you are trying to present. Which has led to a northern hemisphere centric vision of the world that has been burned into our brains. Even though Africa looks roughly the size of Greenland, in fact, it is actually about 14 times larger. Don’t use the standard Mercator map to plan your hiking trip!

Knowing a map’s limitations in perspective points you to where you need to bring context. Consider this passage from Marshall’s book: “Africa’s coastline? Great beaches – really, really lovely beaches – but terrible natural harbors. Amazing rivers, but most of them are worthless for actually transporting anything, given that every few miles you go over a waterfall.”

A lot of maps wouldn’t show you this – the lines that are rivers are all drawn the same. So you’d look at the success the Europeans had with the Danube or the Rhine and think, why didn’t Africans think to use their rivers in the same way? And then maybe you decide to invest in an African mineral company, bringing to the table the brilliant idea of getting your products to market via river. And then they take you to the waterfalls.

The Author/Cartographer

Consider who draws the maps. A map of the modern day Middle East will probably tell you more about the British and French than any inhabitants of the region. In 1916 a British diplomat named Sykes and a French diplomat name Picot drew a line dividing the territory between their countries

based on their interests in the region and not on the cultures of the people living there, or the physical formations that give it form.

Marshall explains, “The region’s very name is based on a European view of the world, and it is a European view of the region that shaped it. The Europeans used ink to draw lines on maps: they were lines that did not exist in reality and created some of the most artificial borders the world has seen. An attempt is now being made to redraw them in blood.”

The map creator is going to bring not only their understanding but also their biases and agenda. Even if your goal is to create the most accurate, unbiased map ever, that intent frames the decisions you make on what to represent and what to leave out. Our relatively new digital mapping makes a decision to respect some privacy at the outset and so Google doesn’t include images of people in its ‘streetview’.

Brotton argues that “a map always manages the reality it tries to show.” And as we have seen before, because there really isn’t one objective reality, maps need to be understood as portraying personal or cultural realities.

“No world map is, or can be, a definitive, transparent depiction of its subject that offers a disembodied eye onto the world.” All maps reflect our understanding of the territory at that moment in time. We change, and maps change with us.

The Territory

This leads to another pitfall. Get the right map. Or better yet, get multiple maps of the same territory. Different explorations require different maps. Don’t get comfortable with one and assume that’s going to explain everything you need. Change the angle.

Derek Hayes, in his Historical Atlas of Toronto, has put together a fascinating pictorial representation of the history of Toronto in maps. Sewer maps, transit maps, maps from before there were any roads, and planning maps for the future. Maps of buildings that were, and maps of buildings that are only dreams. Putting all these together starts to flesh out the context, allowing for an appreciation of a complex city versus a dot on a piece of paper. Maps may never be able to describe the whole territory, but the more you can combine them, the fewer blind spots you will have.

If you compare a map of American naval bases in 1947 with one from 1937, you would notice a huge discrepancy. The number increased significantly. Armed only with this map you might conclude that in addition to fighting in WWII, the Americans invested a lot of resources in base building during the 40s. But if you could get your hands on a map of British naval bases from 1937 you would conclude something entirely different.

As Marshall explains, “In the autumn of 1940, the British desperately needed more warships. The Americans had fifty to spare and so, with what was called the Destroyers for Bases Agreement, the British swapped their ability to be a global power for help in remaining in the war. Almost every British naval base in the Western Hemisphere was handed over.”

The message here is not to give up on maps. They can be wonderful and provide many useful insights. It is rather to understand their limitations. Each map carries the perspective of its creator and is limited by the medium it’s presented in. The more maps you have of a territory, the increased understanding you will have of the complexities of the terrain, allowing you to make better decisions as you navigate through it.

102. Proximate vs Root Causes: Keep Digging to Find the Answer

“Anything perceived has a cause.

All conclusions have premises.

All effects have causes.

All actions have motives.”

— Arthur Schopenhauer

The Basics

One of the first principles we learn as babies is that of cause and effect. Infants learn that pushing an object will cause it to move, crying will cause people to give them attention, and bumping into something will cause pain. As we get older, this understanding becomes more complex. Many people love to talk about the causes of significant events in their lives (if I hadn't missed the bus that day I would never have met my partner! or if I hadn't taken that class in college I would never have discovered my passion and got my job!) Likewise, when something bad happens we have a tendency to look for somewhere to pin the blame.

The mental model of proximate vs root causes is a more advanced version of this reasoning, which involves looking beyond what appears to be the cause and finding the real cause. As a higher form of understanding, it is useful for creative and innovative thinking. It can also help us to solve problems, rather than relying on band-aid solutions. Much of our understanding of cause and effect comes from Isaac Newton. His work examined how forces lead to motion and other effects. Newton's laws explain how a body remains stationary unless a force acts upon it. From this, we can take a cause to be whatever causes something to happen.

For example, someone might ask: Why did I lose my job?

- Proximate cause: the company was experiencing financial difficulties and could not continue to pay all its employees.
- Root cause: I was not of particular value to the company and they could survive easily without me.

This can then be explored further: Why was I not of value to the company?

- Ultimate cause: I allowed my learning to stagnate and did not seek constant improvement. I continued doing the same as I had been for years which did not help the company progress.
- Even further: Newer employees were of more value because they had more up-to-date knowledge and could help the company progress.

This can then help us to find solutions: How can I prevent this from happening again?

- Answer: In future jobs, I can continually aim to learn more, keep to date with industry advancements, read new books on the topic and bring creative insights to my work. I will know this is working if I find myself receiving increasing amounts of responsibility and being promoted to higher roles.

This example illustrates the usefulness of this line of thinking. If our hypothetical person went with the proximate cause, they would walk away feeling nothing but annoyance at the company which fired them. By establishing the root causes, they can mitigate the risk of the same thing happening in the future.

There are a number of relevant factors which we must take into account when figuring out root causes. These are known as predisposing factors and can be used to prevent a future repeat of an unwanted occurrence.

Predisposing factors tend to include:

- The location of the effect
- The exact nature of the effect
- The severity of the effect
- The time at which the effect occurs
- The level of vulnerability to the effect
- The cause of the effect
- The factors which prevented it from being more severe.

Looking at proximate vs root causes is a form of abductive reasoning- a process used to unearth simple, probable explanations. We can use it in conjunction with philosophical razors (such as Occam's and Hanlon's) to make smart decisions and choices.

In Root Cause Analysis, Paul Wilson defines root causes as:

Root cause is that most basic reason for an undesirable condition or problem which, if eliminated or corrected, would have prevented it from existing or occurring.

In Leviathan, Chapter XI (1651) Thomas Hobbes wrote:

Ignorance of remote causes disposeth men to attribute all events to the causes immediate and instrumental: for these are all the causes they perceive...Anxiety for the future time disposeth men to inquire into the causes of things: because the knowledge of them maketh men the better able to order the present to their best advantage. Curiosity, or love of the knowledge of causes, draws a man from consideration of the effect to seek the cause; and again, the cause of that cause; till of necessity he must come to this thought at last that there is some cause whereof there is no former cause.

In Maxims of the Law, Francis Bacon wrote:

It were infinite for the law to consider the causes of causes, and their impulsions one of another; therefore it contented itself with the immediate cause, and judgeth of acts by that, without looking to any further degree.

A rather tongue in cheek perspective comes from the ever satirical George Orwell:

Man is the only real enemy we have. Remove Man from the scene, and the root cause of hunger and overwork is abolished forever."

The issue with root cause analysis is that it can lead to oversimplification and it is rare for there to be one single root cause. It can also lead us to go too far (as George Orwell illustrates.) Over emphasizing root causes is common among depressed people who end up seeing their existence as the cause of all their problems. As a consequence, suicide can seem like a solution (although it is the exact opposite.) The same can occur after a relationship ends, as people imagine their personality and nature to be the cause. To use this mental model in an effective manner, we must avoid letting it lead to self blame or negative thought spirals. When using it to examine our lives, it is best to only do so with a qualified therapist, rather than while ruminating in bed late at night. Finding root causes should be done with the future in mind, not for dwelling on past issues. Expert root cause analysts use it to prevent further problems and create innovative solutions. We can do the same in our own lives and work.

"Shallow men believe in luck or in circumstance. Strong men believe in cause and effect."

— Ralph Waldo Emerson
Establishing Root Causes

Establishing root causes is rarely an easy task. However, there are a number of techniques we can use to simplify the deduction process. These are similar to the methods used to find first principles:

Socratic questioning

Socratic questioning is a technique which can be used to establish root causes through strict analysis. This is a disciplined questioning process used to uncover truths, reveal underlying assumptions and separate knowledge from ignorance. The key distinction between Socratic questioning and normal discussions is that the former seeks to draw out root causes in a systematic manner. Socratic questioning generally follows this process:

1. Clarifying thinking and explaining origins of ideas. (What happened? What do I think caused it?)
2. Challenging assumptions. (How do I know this is the cause? What could have caused that cause?)
3. Looking for evidence. (How do I know that was the cause? What can I do to prove or disprove my ideas?)
4. Considering alternative perspectives. (What might others think? What are all the potential causes?)
5. Examining consequences and implications. (What are the consequences of the causes I have established? How can they help me solve problems?)
6. Questioning the original questions. (What can I do differently now that I know the root cause? How will this help me?)

The 5 Whys

This technique is simpler and less structured than Socratic questioning. Parents of young children will no doubt be familiar with this process, which necessitates asking 'why?' five times to a given statement. The purpose is to understand cause and effect relationships, leading to the root causes. Five is generally the necessary number of repetitions required. Each question is based on the previous answer, not the initial statement.

Returning to the example of our hypothetical laid off employee (mentioned in the introduction), we can see how this technique works.

- Effect: I lost my job.
- Why? Because I was not valuable enough to the company and they could let me go without it causing any problems.
- Why? Because a newer employee in my department was getting far more done and having more creative ideas than me.
- Why? Because I had allowed my learning to stagnate and stopped keeping up with industry developments. I continued doing what I have for years because I thought it was effective.
- Why? Because I only received encouraging feedback from people higher up in the company, and even when I knew my work was substandard, they avoided mentioning it.
- Why? Because whenever I received negative feedback in the past, I got angry and defensive. After a few occurrences of this, I was left to keep doing work which was not of much use. Then, when the company began to experience financial difficulties, firing me was the practical choice.

- Solution: In future jobs, I must learn to be responsive to feedback, aim to keep learning and make myself valuable. I can also request regular updates on my performance. To avoid becoming angry when I receive negative feedback, I can try meditating during breaks to stay calmer at work.

As this example illustrates, the 5 whys technique is useful for drawing out root causes and finding solutions.

Cause and Effect Mapping

This technique is often used to establish causes of accidents, disasters, and other mishaps. Let's take a look at how cause and effect mapping can be used to identify the root cause of a disaster which occurred in 1987: The King's Cross fire. This was a shocking event, where 31 people died and 100 were injured in a tube station fire. It was the first fatal fire to have occurred on the London Underground and led to tremendous changes in rules and regulations. This diagram shows the main factors which led to the fire, and how they all combined to lead to the tragic event. Factors included: flammable grease on the floors which allowed flames to spread, flammable out of date wooden escalators, complacent fire staff who failed to control the initial flames, untrained staff with no knowledge of how to evacuate people, blocked exits (believed to be due to cleaning staff negligence) and a dropped match (assumed to have been discarded by someone lighting a cigarette.)

Once investigators had established these factors which led to the fire, they could begin looking for solutions to prevent another fatal fire. Of course, solving the wrong problem would have been ineffective. Let's take a look at each of the causes and figure out the root problem:

- Cause: A dropped match. Smoking on Underground trains had been banned 3 years prior, but many people still lit cigarettes on the escalators as they left. Investigators were certain that the fire was caused by a match, and was not arson.

Research found that many other fires had begun in the past, yet had not spread. This alone did not explain the severity of this particular fire. Better measures have since been put into place to prevent smoking in stations (although Londoners can vouch for the fact that it still occasionally happens late at night or in secluded stations.)

- Cause: flammable grease on escalators. Research found that this was indeed highly flammable. Solving this would have been almost impossible- the sheer size of stations and the numbers of people passing through them made thorough cleaning difficult. Solving this alone would not have been sufficient.
- Cause: wooden escalators. Soon after the fire, stations began replacing these with metal (although it took until 2014 for the entire Underground network to replace every single one.
- Cause: untrained staff. This was established to be the root cause. Even if the other factors were resolved, the lack of staff training or access to fire fighting equipment still left a high risk of another fatal incident. Investigations found that staff were only instructed to call the Fire Brigade once a fire was out of control, most had no training and little ability to communicate with each other. Once this root cause was found, it could be dealt with. Staff were given improved emergency training and better radio tools for communicating. Heat detectors and sprinklers were fitted in stations.

From this example, we can see how useful finding root causes is. The lack of staff training was the root cause, while the other factors were proximate causes which contributed. From this information, we can create this diagram to illustrate the relationship between causes.

"All our knowledge has its origins in our perceptions ... In nature, there is no effect without a cause ... Experience never errs; it is only your judgments that err by promising themselves effects such as are not caused by your experiments."

- Leonardo da Vinci

How We Can Use This Mental Model as Part of our Latticework

- Hanlon's Razor — This mental model states: never attribute to malice that which can be attributed to incompetence. It is relevant when looking for root causes. Take the aforementioned example of the Kings Cross fire. It could be assumed that staff failed to control the fire due to malice. However, we can be 99% certain that their failure to act was due to incompetence (the result of poor training and miscommunication.) When analysing root causes, we must be sure not to attribute blame where it does not exist.
- Occam's Razor — This model states: the simplest solution is usually correct. In the case of the fire, there are infinite possible causes which could be investigated. It could be said that the fire was started on purpose, the builders of the station made it flammable on purpose so they would be required to rebuild it that the whole thing is a conspiracy theory and people actually died in an alternate manner. However, the simplest solution is that the fire was caused by a discarded match. When looking for root causes, it is wise to first consider the simplest potential causes, rather than looking at everything which could have contributed.
- Arguing from first principles — This mental model involves establishing the first principles of any given area of knowledge- information which cannot be deduced from anything else. Understanding the first principles of how fire spreads (such as the fire triangle) could have helped to prevent the event.
- Black swans — This model, developed by Nassim Taleb is: “an event with the following three attributes. First, it is an outlier, as it lies outside the realm of regular expectations because nothing in the past can convincingly point to its possibility. Second, it carries an extreme impact.... Third, in spite of its outlier status, human nature makes us concoct explanations for its occurrence after the fact, making it explainable and predictable.” The King's Cross fire was a black swan- surprising, impactful and much analyzed afterwards. Understanding that black swans do occur can help us to plan for serious events before they happen.

- Availability bias — This model states: we misjudge the frequency of events which have happened recently and information which is vivid. Imagine a survivor of the Kings Cross fire who had also been on a derailed train a few months earlier. The intensity of the two memories would be likely to lead them to see travelling on the Underground as dangerous. However, this is not the case – only one in 300 million journeys experience issues (much safer than driving.) When devising root causes, we must be sure to consider all information, not just that which comes to mind with ease.
- Narrative fallacy — This model states: we tend to turn the past into a narrative, imagining events as fitting together in a manner which is usually false.
- Hindsight bias — This model states: we see events as predictable when looking back on them.
- Confirmation bias — This model states: we tend to look for information which confirms pre-existing beliefs and ideas.

103. Leverage: Gaining Disproportionate Strength

"It is easier to conquer than to administer.

*With enough leverage, a finger could overturn the world;
but to support the world, one must have the shoulders of Hercules."*

— Jean-Jacques Rousseau, *The Social Contract*

The Basics

A good place to begin understanding the concept of leverage is the etymology of the word. We can trace its origins back to the Proto-Indo-European 'legwh' which described something light, agile, or easy. From this, the Latin 'levare' formed, which referred to something that was 'not heavy.' But the word absorbed into English in the 14th century from Old French, where 'levier' referred to raising something (hence the reflexive verb, 'se lever' which, in general, is used in the context of getting up in the morning.) So in essence, leverage refers to making something light by raising it in a specific manner.

The fusion of these two ideas perfectly describes a physical lever- a pole connected to a fulcrum which serves to create additional strength or force. A lever does not bend or create additional friction.

Three main types of physical levers have been identified

1. Levers with the fulcrum in the middle. A force is applied on one side and the load is on the other side (such as a crowbar.)
2. Levers where the load is placed in the middle and the force is applied on one side, with the fulcrum located on the other (such as a bottle opener.)
3. Levers where the force is applied in the middle (such as our lower jaw bones.)

Archimedes is credited with establishing the concept of leverage, over 2000 years ago. He famously stated that, given a lever long enough and enough distance, he could lift the earth.

In On the Equilibrium of Planes, Archimedes wrote: "Magnitudes in equilibrium at distances are reciprocally proportional to their weights."

However, the Peripatetic School (the followers of Aristotle) wrote of levers before the birth of Archimedes. In *Mechanica*, a work believed to have been written by members of this school of thought, they state:

Why is it that small forces can move great weights by means of a lever, as was said at the beginning of the treatise, seeing that one naturally adds the weight of the lever? For surely the smaller weight is easier to move, and it is smaller without the lever. Is the lever the reason, being equivalent to a beam with a cord attached below, and divided into two equal parts? For the fulcrum acts as the attached cord: for both these remain stationary, and act as a centre. For since under the impulse of the same weight the greater radius from the centre moves the more rapidly, and there are three elements in the lever, the fulcrum, that is the cord or centre, and the two weights, the one which causes the movement, and the one that is moved : now the ratio of the weight moved to the weight moving it is the inverse ratio of the distances from the centre. Now, the greater the distance from the fulcrum, the more easily it will move. The reason has been given before that the point further from the centre describes the greater circle, so that by the use of the same force, when the motive force is farther from the lever, it will cause a greater movement.

Like many of our mental models, leverage is a scientific concept which has applications in many other areas.

Leverage is an idea which humans have used to great effect for thousands of years, enabling them to gain disproportionate strength. For example, the ancient Egyptians used levers to lift stones weighing up to 100 tons in order to build the pyramids and obelisks.

Many of humanity's tools, used for centuries all over the world, incorporate levers- scissors, pliers, door handles, wheelbarrows, fishing rods and more.

The concept of leverage has been applied to other areas over the last century or so.

In Decision Making, Alan C McLucas defines leverage and leverage points as:

Leverage is built on the notion that small, well-focused actions can sometimes produce significant, enduring improvements if they are applied in the right place. Tackling a difficult problem is often a matter of seeing where the high leverage lies.

... A leverage point is where a small difference can make a large difference. Leverage points provide kernel ideas and procedures for formulating solutions. Identifying leverage points helps us: create new courses of action, develop increased awareness of those things that may cause a difficult before there are any obvious signs of trouble and figure out what is causing a difficult.

Leverage in Negotiations and Business

"You don't convince people by challenging their longest and most firmly held opinions. You find common ground and work from there. Or you look for leverage to make them listen. Or you create an alternative with so much support from other people that the opposition voluntarily abandons its views and joins your camp."

— Ryan Holiday, *The Obstacle Is the Way*

Roger J Volkema provides an example of how people use leverage for their own benefit in negotiations:

It is one of the hottest days of the year and something is wrong with your refrigerator...the temperature seems too warm. You contact a repairman who promises to come that afternoon. You ask about the likely cost. He says it could be around \$80... The repairman arrives, late in the afternoon. He believes the problem is with your freezer. He takes out all the frozen foods, unscrews panels, cuts wires. There is the problem: a coil had gone bad. It will cost you \$230. Sound familiar? You are now at the mercy of the repairman. You know little to nothing about freezer coils...you lack a choice and agree to pay the price. This story has been repeated dozens of times in your life...in each case, you felt at a disadvantage... They had leverage.

This tactic is used commonly by businesses. Buying a drink or snack on an airplane will always be expensive because the airline knows people lack an alternative, giving them the leverage. Spotify and Youtube can subject users to endless advertisements because the service is otherwise free and this gives them control. Companies with a monopoly (due to a patent, for example) can charge more because they own a particular market. A doctor can present an extortionate bill because we have no option to return the service ("hey doc, can you undo these stitches? I can get a cheaper operation elsewhere.")

Volkema goes on to explain the key principles of leverage:

1. Leverage is based on perceptions. If a party to a negotiation has an advantage and nobody perceives that the advantage exists...there is no leverage. This is especially true for the party with the disadvantage...Thus, it is perceived cost, real or imaginary that enables leverage.

... 2. Leverage is dynamic. Leverage can change as quickly as new information becomes available...These sorts of changes occur during formal business negotiations as well. If, for example, information central to an upcoming bidding process known only to one company becomes available to the other company, then leverage among companies has shifted.

...3. Leverage is situation specific...The aforementioned company with privileged information might have an advantage over another company, but in another situation, the advantage could be reversed (for example, the second company has just made a technical breakthrough that will revolutionize the industry.) Sometimes the situations that create leverage overlap or can be linked in some way.

...4. Leverage is a social or relational construct. Therefore, one has advantage over another individual only as long as the relationship exists. If one part leaves the relationship...leverage ceases to exist...Without another party, it is like being on a seesaw by yourself.

In one of his iconic letters to shareholders, Warren Buffett declared: “Don’t ask the barber whether you need a haircut.” To do so transfers leverage to the barber, who will always say yes. To retain leverage would necessitate telling the barber you certainly do not need a haircut, leading them to offer you an attractive deal.

Anyone who has ever haggled at a market or with a salesperson will understand the principle of using leverage in a negotiation. The trick is to declare their product or service to be so flawed and worthless that you are doing them a favor by buying it. Subsequently, the next step is usually to offer a low price which they counter with a slightly higher one that is still much lower than the asking price.

Another amusing example of leverage in negotiation comes from Jarod Kintz:

Money is not equal for all people. A strong personal brand adds more lift and leverage. One dollar from me may buy a soda from a car dealership, but one dollar from Justin Bieber may get him a Ferrari. And they would pay him to drive away.

Related Mental Models and Concepts

- **Critical mass** — Also known as a boiling point or tipping point, critical mass is the point where something (an idea, belief, trend, virus, behavior etc) is prevalent enough to grow at an exponential rate. It becomes contagious and is everywhere in a short span of time. We can combine this mental model with leverage to understand how drastic changes can be created with minimal effort. The critical mass serves as a lever. Imagine a teacher who wants to encourage the 30 pupils in her class to read more. Research has shown that just 10% of a population are necessary to form a critical mass. Rather than seeking to convince all 30 pupils to read more, she needs to persuade 3 popular ones. Once they begin reading more, the teacher can leverage them to spread their new love of books. Once this is achieved, it can pass on to the rest of the school.
- **Power law** — A power law is a relationship between two things when a change in one can lead to a large change in the other, regardless of the initial quantities. In the case of leverage, a power law relationship exists between the effort exerted on the lever (actual or metaphorical) and the outcome. For example, consider two children on a seesaw. If both children are an equal weight, the seesaw will go up and down with ease. If one goes away and a heavier child replaces them, a small difference in their weights will lead to a large increase in the speed at which the seesaw moves.
- **Pareto’s principle** — This principle states that 80% of outcomes are the result of 20% of inputs. Recognizing the 20% can provide us with a great deal of leverage. If a business receives 80% of its income from 20% of customers, the latter group can be leveraged to increase profits (e.g. by offering special deals and treatment to them, increasing their loyalty.) If 20% of the foods we eat comprise 80% of our diets, we can leverage these to improve our health (e.g. if a person eats bread each day, they could switch from white bread to wholegrain.)
- **Tribal leadership** — This concept involves leveraging ‘tribes’ within an organisation to further an agenda and grow a company culture. Tribes go through five stages towards maximum productivity and each has different leverage points.
- **Outsourcing** — Outsourcing certain tasks (such as cleaning or making transcripts) enables us to leverage one asset – money- to free up more time and make more money as a result.

- Commitment consistency bias — We have a desire to remain consistent with our past behaviour. Companies and manipulative people leverage this cleverly. If our favorite coffee shop raises their prices, we are unlikely to switch to somewhere else- after all, we have a loyalty card and the baristas know our usual order. If we realize the interest rates at our bank are lower than elsewhere, we are unlikely to change- we must have chosen them in the first place for a good reason. If an old friend suddenly becomes obnoxious and insulting, we are unlikely to stop spending time with them, due to the sunken costs of all the time spent together in the past
- Activation energy — Activation energy is the initial amount of energy necessary to commence a chemical reaction. We can apply this to leverage – the energy required to move the lever is the activation energy required to create movement.

104. Mutually Assured Destruction: When Not to Play

Mutually assured destruction is a military mental model with powerful applications in life and business. It refers to a situation where two parties are in a stalemate, and neither can make a move without causing their own destruction. Here's why this happens and how we can avoid putting ourselves in situations where playing means losing.

"A strange game. The only winning move is not to play."

— Professor Falken in the 1983 Movie *War Games*

The History of Mutually Assured Destruction

On the day in 1945 that Robert A Lewis, copilot of the B-29 Superfortress dropped the first atomic bomb on Hiroshima, he wrote six agonizingly poignant words in his log book: "My God, what have we done?"

What exactly had he done? His question is more complex than it seems.

If we look at that act in the literal sense, Lewis had just dropped 'Little Boy', the first of two atomic bombs which killed an estimated 129,000+ people. An accurate figure of the death toll is impossible to establish. This act was ordered by President Truman at the end of World War 2, to end the invasion of Japan and create 'peace.'

Less than a week after the bombing of Nagasaki, Japan surrendered and World War 2 ended a short time later.

Nuclear fission was first discovered in 1938, and scientists soon theorized that the development of atomic bombs was plausible. After hearing of Nazi plans to develop nuclear weapons, the US began its own research projects.

The Manhattan Project was set up and researchers developed two types of atomic bomb. When Japan refused to surrender, the decision was made to use the new weapon on two major cities. It achieved the desired effect and the war was finally over.

In his declaration to the Japanese people upon the topic of surrender, Emperor Hirohito stated:

The enemy now possesses a new and terrible weapon with the power to destroy many innocent lives and do incalculable damage. Should we continue to fight, not only would it result in an ultimate collapse and obliteration of the Japanese nation, but also it would lead to the total extinction of human civilization.

Controversy is still prevalent (and doubtless always will be) as to the justification of the bombing. Many scholars debate if it caused or prevented more deaths. However, the big question is not 'what have we done?' but 'what will we do?' Dropping the first atomic bomb did not just open a macabre Pandora's box, it also forced humanity to see the possibility that we will destroy ourselves and this entire planet in the process of settling disputes between nations.

As of 2016, 174,000 survivors of the bombing are still alive, living with the physical, psychological, and social consequences. The after effects spread far beyond Japan—indeed the ripples of the first use of nuclear weapons affect us all, even if not in an obvious way.

We have a strange tendency to forget that we are all — every human on earth — in this together. As it stands — for now, Elon — Earth is the only planet we have to live on. We can segregate it by national borders, but these are man-made ideas, not physical separations. This is where the concept of mutually assured destruction comes in. It happens to be one of the few instances where we can all agree on something: we must not wipe ourselves out and destroy our planet.

Why The Concept of Mutually Assured Destruction Matters

The concept of mutually assured destruction was first described by Wilkie Collins, a 19th century English author. In a letter written at the time of the Franco-Prussian war, over 70 years before the first atomic bomb dropped, Collins wrote:

I am, like the rest of my countrymen, heartily on the German side in the War. But what is to be said of the progress of humanity? Here are the nations still ready to slaughter each other, at the command of one miserable wretch whose interest is to set them fighting! Is this the nineteenth century? or the ninth? Are we before the time of Christ or after? I begin to believe in only one civilizing influence – the discovery one of these days, of a destructive agent so terrible that War shall mean annihilation, and men's fears shall force them to keep the peace.

It seems that Collins was very much ahead of his time.

Alfred Nobel (founder of the Nobel Prize and the inventor of dynamite) recognized this too, saying:

The day when two army corps can annihilate each other in one second, all civilized nations, it is to be hoped, will recoil from war and discharge their troops.

For most of human history, combat was hand to hand. People fought face to face, using swords, knives, bayonets, clubs, and other handheld weapons.

Humans have always fought each other with a viciousness largely unique to our species. Archaeological digs have uncovered evidence of genocides as far back as 5000 BC. As our intelligence and technology has advanced, so has our capacity to kill each other in large numbers.

Warren Buffett pointed this out in a [CNN interview](#).

You know, thousands of years ago we had psychotics and we had religious fanatics and we had megalomaniacs. But about the most they could do was throw a stone at somebody if they wished evil on them. Today, since 1945, the ability to inflict evil, or harm, on other people in huge numbers has grown exponentially.

Nuclear weapons are the culmination of this progress towards methods of wiping out huge numbers of people with minimal effort.

After the US dropped the first atomic bombs on Japan, other countries raced to develop their own. The USSR had hydrogen bombs within 8 years. Both developed their technology to the point where either of them had the ability to basically decimate the entire world if the leaders chose to. It goes without saying that a nation had never held that type of power before.

By the 1960s, the concept of mutually assured destruction (hereafter referred to as MAD) was crystallized. Both the US and the USSR could bring about the end of humanity (including themselves), but neither wanted to. This led to a stalemate, essentially stating 'I won't if you don't.' For either to attack would mean their own destruction, defeating the purpose of war. Ironically enough, the concept of MAD has led to relative peace between countries with nuclear capabilities. Tension is still prevalent, as each must keep up with the developments of the other to ensure continued equality.

During the Cold War, MAD was probably responsible for the lack of serious conflict between the US and USSR. The US kept a fleet of airplanes airborne non-stop, ready to drop nuclear bombs on the USSR at a moment's notice, should they strike first. Even if the USSR tried to destroy the entire US, they would still be able to retaliate using airplanes. However, airplanes were logistically and financially difficult to sustain and the US began to look for alternatives. Ballistic missile submarines were adopted as a solution. Submarines are also operated by the UK, France, China, India, and Russia. While world peace is certainly a long way off, this nuclear fleet provides a semblance of global stability.

The Key Components of Mutually Assured Destruction

There are several key components of the doctrine of MAD:

- Both sides in a combat must have the capacity to completely destroy the other. Any inequality in their power has the potential to tip the balance. The US and USSR have since developed more nuclear technology – guided missile systems, and weapons sprinkled around the globe in submarines. Neither side can have sufficient nuclear shelters to protect substantial numbers of people in the event of an attack. If

one side can cause a degree of destruction which would prevent a counterattack, the concept of MAD is not applicable.

- Both sides must have a genuine reason and motivation to believe that the other would be willing to destroy them. Any doubt in this area is dangerous.
- Both sides must be able to detect attacks with perfect accuracy. This necessitates the ability to know when a nuclear attack has occurred, without any errors. If one side uses stealth detonation (such as bombs smuggled into a country), MAD is not assured.
- Both sides must know exactly where a threat originates from. One serious problem is the border between China and Russia, both of which have nuclear weapons. Parts of China actually protrude into Russia, which could lead to complications as one could make it appear as if an attack originated from the other.
- Both sides must act rationally (in short, all those with power must be able to act like adults and take the concept of MAD seriously.) A rogue leader with a great deal of power and a disregard for human life beyond their own would have the potential to start a nuclear war. A chilling fact is that this came close to happening during the Cuban Missile Crisis when a lone submarine commander attempted to detonate a nuclear missile. That single act of insanity might have easily meant that you could not be reading this right now. Carl Sagan sums this up: "The nuclear arms race is like two sworn enemies standing waist-deep in gasoline, one with three matches and the other with five...every thinking person fears nuclear war and every technological state plans for it. Everyone knows it is madness and every nation has an excuse."

As that list shows, the concept is somewhat fragile and requires constant vigilance and innovation to maintain. There is also the ever prevalent risk of accidental or terrorist detonation.

The Potential Consequences of Mutually Assured Destruction

Thankfully, we do not have a clear picture of the potential consequences of MAD playing out. We do have an idea of what they would be – a nuclear apocalypse. Although the concept of a nuclear apocalypse has become almost comical due to its prevalence in science fiction, it is important to understand that it remains a very real possibility.

Should a nuclear war break out, it is believed that the result would be the collapse of human civilization, as much or all of the planet becomes unsuitable for life, cities are erased and technology becomes unusable.

Any people who manage to survive the initial blast(s), would have a poor chance of long-term survival due to firestorms, a possible nuclear winter and the effects of radiation.

Combine that with a famine and lack of law enforcement or medical care for survivors- the outlook would be bleak, to say the least. Substantial numbers of people could survive a global world war, although it is unlikely that we would be able to overcome the secondary impact. In any case, what would human life be without any economic or political structure or any of the other important concepts we take for granted?

Once again, it is difficult yet important to take this concept seriously as it seems so unrealistic. When we take into account the fact that at least 15,000 nuclear weapons are held worldwide, the chances are higher than we imagine.

In Bomb Steve Sheinkin writes:

"Consider this. A study published in Scientific American in 2010 looked at the probable impact of a "small" nuclear war, one where India and Pakistan each dropped fifty atomic bombs. The scientists concluded that the explosions would ignite massive firestorms,

sending enormous amounts of dust and smoke into the atmosphere. This would block some of the sun's light from reaching the earth, making the planet colder and darker – for about ten years. Farming would collapse, and people all over the globe would starve to death. And that's if only half of one percent of all the atomic bombs on earth were used. In the end, this is a difficult story to sum up. The making of the atomic bomb is one of history's most amazing examples of teamwork and genius and poise under pressure. But it's also the story of how humans created a weapon capable of wiping our species off the planet. It's a story with no end in sight. And, like it or not, you are in it."

The mental model of mutually assured destruction can be particularly useful outside of warfare.

Consider two mafia members who can't tell on one another. Or when companies obtain a large patent portfolio but don't pursue legal action against competitors with large patent portfolios.

Competition

Ask yourself, "Where are we competing where everyone is effectively the same?" and "What would happen if we got into a heated price war ... could we destroy our competitor? Would they destroy us?" Ideally, you can avoid these situations but if you can't you should, at least, be aware of them.

You can learn a lot just from identifying the situations where you're in a version of mutually assured destruction. For the model to work as a thinking tool you don't have to go as far as destruction. You can think in terms of ability for competitors to cause you pain or for you to cause them pain.

Trust

One of the ways we understand trust is through mutually assured destruction.

Consider two businesses engaged in tax fraud together. Either could rat the other out, knowing full well they would then be turned over.

The list goes on and on.

In the end, while you should try to avoid situations of mutually assured destruction, they can promote good behavior between parties. However, it only takes one party in a situation to start a massive chain reaction with usually catastrophic outcomes.

105. People Don't Follow Titles: Necessity and Sufficiency in Leadership

"Colonel Graff: You have a habit of upsetting your commander.

Ender Wiggin: I find it hard to respect someone just because they outrank me, sir."

— Orson Scott Card

Many leaders confuse necessary conditions for leadership with sufficient ones.

Titles often come with the assumption people will follow you based on a title. Whether by election, appointment, or divine right, at some point you were officially put in the position. But leadership is based on more than just titles.

Not only do title-based leaders feel like once they get the title that everyone will fall in line, but they also feel they are leading because they are in charge — a violation of the golden rules of leadership. This makes them toxic to organization culture.

A necessary condition for leadership is trust, which doesn't come from titles. You have to earn it.

Necessary conditions are those that must be present, but are not, on their own, enough for achievement. This is an exceptional mental model that will help you achieve outcomes. Perhaps an easy example will help illuminate. Swinging at a pitch in baseball is necessary to hit the ball, but not sufficient to do so.

War offers another example. It's necessary to know the capabilities of your enemy and their positions, but that is not sufficient to win a battle.

Leadership can be very similar. Being in a position of leadership is necessary to lead an organization, but that is not sufficient to get people moving towards a common goal. Titles, on their own, do not confer legitimacy. And legitimacy is one of the sufficient conditions of leadership.

If your team, organization, or country doesn't view you as legitimate you will have a hard time getting anything done. Because they won't work for you, and you can't do it all yourself. Leadership without legitimacy is a case of multiply by zero.

There is a wonderful example of this, from the interesting history of the Mongolians. In his book The Secret History of the Mongol Queens, Jack Weatherford tells an amazing story of the unlikely, but immensely successful, leadership of Manduhai the Wise.

250 years after Genghis Khan, the empire was in fragments. The Mongols had retreated into their various tribes, often fighting each other and nominally ruled by outsiders from China and the Middle East. There was still a Khan, but he exercised no real power. The Mongol tribes were very much at the mercy of their neighbors.

In 1470 the sitting Khan died, survived only by a junior wife. There were immediate suitors vying for her affection because by marrying her the title of Khan could be claimed. Her name was Manduhai. Instead of choosing the easy path of remarriage and an alliance, she decided to pursue her dream of uniting the Mongol nation.

First, she had to choose a consort that would allow her to keep the title of Queen. There was one remaining legitimate survivor of Genghis Khan's bloodline – a sickly 7-year-old boy. Orphaned as a baby and neglected by his first caregiver, he had been under Manduhai's protection for a few years. Because of his lineage, she took him to the Shrine of the First Queen and asked for divine blessings in installing him as the Great Khan. They would rule together, but clearly, due to his age and condition, she would be in charge.

Although her words would be addressed to the shrine, and she would face away from the crowd, there could be no question that, in addition to being the spiritual outcry of a pilgrim, these words constituted a desperate plea of a queen to her people. This would be the most important political speech of her life.

She was successful in securing the appointment. But Manduhai understood that the title of Great Khan for the little boy and Khatun (Queen) for her would not be enough. She

needed the support of all the Mongol tribes to give the titles legitimacy, and here there were a significant number of obstacles to overcome.

Twice before in the previous generations, boys of his age had been proclaimed Great Khan, only to be murdered by their rivals before they could reach full maturity. Other fully grown men who bore the title were also ignominiously struck down and killed by the Muslim warlords who tried to control them.

First Manduhai had to keep herself and the boy, Dayan Khan, alive. Then she had to demonstrate that they were the right people to unite the Mongol tribes and ensure prosperity for all. This would take both physical battles and a strategic understanding of how to employ little power for great effect. Her success was by no means guaranteed. *Throughout their reign, as on this awkward inaugural day, they frequently benefited from the underestimation of their abilities by those who struggled against them. In the world where physical strength and mastery of the horse and bow seemed to be all that really mattered, no one seemed to anticipate the advantages of patient intelligence, careful planning, and consistency of action.*

It was these traits that led Manduhai to carefully craft her plan of action. She needed to position herself as a true leader that could unite the Mongol tribes.

Vows, prayers, and rituals before a shrine added much needed sacred legitimacy to Dayan Khan's rule, but without force of arms, they amounted to empty gestures and wasted breath. Only after demonstrating that she had the skill to win, as well as the supernatural blessing to do so, could Manduhai hope to rule the Mongols. She had enemies on every side, and she needed to choose her first battle carefully. She had to confront each enemy, but she had to confront each in its own due time. Manduhai needed to manage the flow of conflicts by deciding when and where to fight and not allowing others to force her into a war for which she was not prepared or stood little chance of winning.

She made an important strategic alliance with one of the failed suitors, a popular and intelligent general who controlled the area immediately east of her power base. Then she went to battle to secure her western front. Some tribes supported her from the outset, due to the spiritual power of her partnership with the boy, the 'true Khan'. The rest she conquered, support snowballing behind her.

In addition to its strategic importance, the western campaign against the Oirat was a notable propaganda victory, demonstrating that Manduhai had the blessing of the Shrine of the First Queen and the Eternal Blue Sky. Manduhai showed that she was in control of her country.

Grinding it out in the trenches inspired support. Manduhai demonstrated the courage and intelligence to lead and to provide what her people needed. She was not an empire builder, seeking to conquer the world. Rather, she was pragmatic desiring to unify the Mongol nation to ensure they had the means to thwart any future attempt at takeover by a foreign power.

In contrast to the expansive territorial acquisition favored by prior generations of steppe conquerors, Manduhai pursued a strategy of geographic precision. Better to control the right spot rather than be responsible for conquering, organizing, and running a massive empire of reluctant subjects. ... Rather than trying to conquer and occupy the extensive links of the Silk Route or the vast expanse of China, she sought to conquer just the strategic spot from which to control them.

Her story teaches us the difference between necessity and sufficiency when it comes to leadership.

Manduhai ticked all the necessary boxes, being a Queen, choosing a descendant of Genghis Khan to rule by her side, and asking for meaningful spiritual blessings. While necessary these were not sufficient to rule. To actually be accepted as a leader, she had to prove herself both on the battlefield and in strategic negotiations. She understood that people would only follow her if they believed in her, and saw that she was working for

them. And finally, she also considered how to use her leadership to create something that would continue long after she had gone.

Manduhai concentrated the remainder of her life in protecting what she had accomplished and making certain that the nation could sustain itself after her departure. With the same assiduous devotion she had applied to the battlefield and the unification of the Mongol nation, Manduhai and Dayan Khan now set to the reorganization of the Mongol government and its protection in the future.

In this, she succeeded. She cemented her power as Queen by ultimately working for the peace and prosperity of the entire Mongol nation. Perhaps this is why she is remembered by them as Mandukhai the Wise.

106. Counterinsurgency: Fighting Back

The Basics

For an accurate definition of counterinsurgency (and the flipside, insurgency), we can look to one of the definitive texts on the topic.

In Counterinsurgency, David Kilcullen writes:

An insurgency, according to the current US military field manual on the subject is 'an organized movement aimed at the overthrow of a constituted government through the use of subversion and armed conflict... Stated another way, an insurgency is an organized, protracted politico-military struggle designed to weaken the control and legitimacy of an established government, occupying power or other political authority while increasing insurgent control.' The same field manual defines counterinsurgency as the 'military, paramilitary, political, economic, psychological and civic actions taken by a government to defeat insurgency.' Counterinsurgency therefore is an umbrella term that describes the complete range of measures that governments take to defeat insurgencies... there is no template, no single set of techniques for countering insurgencies. Counterinsurgency is simply whatever governments do to defeat rebellions.

In essence, counterinsurgency involves the attempts governments make to restore peace. The aim is to minimize civilian deaths while strengthening the influence of governments. No rulebook or particular strategy exists-counterinsurgent forces combine psychological, military, economic and political techniques. In the end, counterinsurgents try to create stability in the least harmful way possible, allowing a country to return to normal functioning.

How Counterinsurgency Works

Counterinsurgency is complex and delicate, full of metaphorical minefields.

Combat can be viewed as a sped up evolutionary process, wherein both sides adapt constantly in response to the behavior of the other. Each learns to defend themselves and to predict risks to their agenda.

One critical, omnipresent element is the effort to forge partnerships with civilian populations.

We often see photographs of soldiers handing out toys and sweets to children in war zones. What seems like a simple act of kindness is actually a clever military tactic. Small efforts like that compound to create trust and subsequent cooperation. The more a population sides with counterinsurgents, the less power insurgents have.

Kilcullen writes:

Insurgents cannot operate without the support... of the local population... violence against noncombatant civilians by security forces, whether intentional or accidental is almost always entirely counterproductive.

One common method is to force the population to move to a different area, making insurgents easier to identify. Civilians may be forced to carry ID and have it checked at regular intervals. Food supplies for insurgents can be cut off, such as through the use of Agent Orange in Vietnam to kill crops.

In Counterinsurgency Warfare, David Galula expands upon this key component of counterinsurgent efforts:

The population represents this new ground. If the insurgent manages to dissociate the population from the counterinsurgent... he will win the war... Thus the battle for the population is a major characteristic of the revolutionary war.

Other theorists have explained that the objective is to gain support, not terrain. Another typical technique is the restoration of as much stability as possible to reduce the power of insurgents.

Galula writes:

Prompting disorder is a legitimate objective for the insurgent. It helps disrupt the economy, hence to produce discontent; it serves to undermine the strength and the authority of the counterinsurgent. Moreover, disorder- the normal state of nature- is cheap to create and very costly to prevent.

Populations of people tend towards entropy without coherent political, economic, social and educational structures. Insurgents aim to disrupt these, while counterinsurgents aim to rebuild them.

Looking at conflicts he has experienced, Galula considers the perspectives of both sides. Despite the liquid nature of counterinsurgency, he outlines the key principles. Firstly, the goal is to gain support rather than control. Once a population supports its governing bodies, conflict becomes unlikely. Even an uncooperative population must be kept safe while mutual trust builds. Galula advocates starting in one location and spreading out, using it as a safe base until the surrounding areas can be controlled. This is known as the 'oil spot' strategy. He sums up his attitude thus: "Build (or rebuild) a political machine from the population upwards."

Counterinsurgency techniques tend to be formed through trial and error, based on our understanding of a particular location and feedback loops. As David Morris, a former Marine, put it: "In order to learn a lesson, you had to lose somebody."

According to Dr. Lorenzo Zambenardi, counterinsurgency involves three main goals:

1. The protection of counterinsurgent forces. A classic rule for firefighters states that the safety of the rescuer is always more important than that of the person being rescued. The same applied to counterinsurgents.

2. The formation of a separation between insurgents and non-combative civilians.

Counterinsurgents must create a physical or mental barrier. Sometimes this is done by moving noncombatants to a different location or providing them with ID cards. Separation can also be psychological – teaching people that they should not side with insurgents and are not part of the conflict. Understanding of the 'human terrain' is required

3. The destruction or conversion of insurgents. This might involve undermining power structures, cutting off resources or strategic assassinations.

The Origin of Counterinsurgency: Santa Cruz de Marcenado

We can trace the roots of counterinsurgency back to the 18th century when Santa Cruz de Marcenado wrote of the concept in Reflexiones Militaires.

Santa Cruz wrote that a leader must win the trust of a population, rather than battering them into submission with physical force- a somewhat modern attitude for the early 1700s. Recognizing that rebellion is a risky endeavor, he cautioned leaders to realize that people do not revolt without strong logic.

Santa Cruz's writing was based on his own experiences during the war of the Spanish Succession (1701-1714.) The conflict occurred both within Spain and with rival nations. He would ultimately lose his life in a Spanish colonial war.

Santa Cruz's principles, outlined in the text, are still relevant today. He encouraged leaders to take preventative measures against insurgencies, namely the fair treatment of all.

People must be respected and allowed to continue their traditions and cultural practices wherever possible. Counterinsurgent forces must behave according to strict protocol, with punishments for anyone who express cruelty. However, Santa Cruz did still advocate cutting off food supplies to a population and using intense military force to end insurgencies in the shortest time possible.

The Impact of Frank Kitson on Counterinsurgency

The works of Frank Kitson have foundational importance in counterinsurgent doctrine.

Kitson is a controversial figure, due to his role in assassinations and the Bloody Sunday massacre during the Troubles in Northern Ireland. He was not adverse to discarding legal and ethical considerations for the sake of his goals as a leader.

Expanding upon the ancient writings of Sun Tzu, he advocated mirroring insurgent behavior in order to understand them. Kitson also made use of spies within insurgent groups to garner information. His strategies created uncertainty and confusion amongst rival power structures, as well as destabilizing their public image.

One soldier summed up the tactics used under Kitson's guidance: "We were not there to act like an Army unit, we were there to act like a terror group." His theories stress the importance of the media in counterinsurgency.

Kitson's theories formed the basis of the way the British counterinsurgents handled the Northern Irish conflict. A counterinsurgent group (the MRF) targeted the insurgents (the IRA) by essentially using enhanced versions of their own tactics against them. Many of their strategies were morally repugnant.

Civilians were killed to show the population that the IRA could not protect them. Innocent people were shot at random to create further unrest.

As this illustrates, counterinsurgency is a complex, delicate technique which often leads to moral dilemmas. It is undeniable that Kitson's strategies led to many innocent deaths.

However, the risk was high at the time of unrest spreading to the rest of the UK, with the potential for huge numbers of casualties. Counterinsurgents in Northern Ireland aimed to quell this risk as soon as possible before the situation worsened. Kitson saw the transgression of legal boundaries as necessary during counterinsurgency.

There are always going to be controversies surrounding counterinsurgency. In part, this is due to the confused relationship between cause and effect during the conflict.

No one can quite say what led to or ended a period of unrest. Consequently, the efficacy of counterinsurgency is difficult to gauge. Individuals such as Kitson often come under fire, as the public seeks to blame someone for the loss of lives. Removed from the situation, we cannot expect to understand counterinsurgent motivations. We also cannot know what the consequences of acting differently (or not at all) would have been.

Examples Of Counterinsurgency in Action- Malaya

Between 1948 and 1960, an insurgency broke out in Malaya. The causes brewed for a while- British taxes led to a rise in poverty and tension between Malays and Chinese people working in traditional industries. Japanese occupation during the Second World War further complicated matters, forcing Malays to focus on subsistence farming (rather than exporting goods.) By the time the Japanese withdrew, severe famine-racked the country and the economy was at its historic worst. Protests broke out from 1946 onwards as a result.

The British were motivated to protect Malaya, due to the tin and rubber industries. As occurs all too often, the British administration attempted to counteract protests with violence which only worsened the tension. Eventually, a critical mass of rebellious people formed.

The tipping point occurred in June 1948, when insurgents killed 3 European plantation managers. British counterinsurgents were brought in to undermine Malayan Communist and left-wing groups. Once again, this further aggravated insurgents who clustered in rural areas to plan attacks on mines and plantations.

The British counterinsurgents attempted gentler measures, offering money to insurgents who agreed to surrender. Even so, over 4000 insurgents refused to disband and went into hiding. Echoing Santa Cruz's statement that people only rebel for a good reason, Chinese people in Malaya were treated as second class citizens and denied rights. Supporters (mostly Chinese immigrants) assisted them and many joined the insurgents, who organized themselves into ranks, with their own media, education and supply chains. Even so, they were never able to establish any real control over the nation due to British counterinsurgency. This consisted of a number of strategies. Locations which were probable targets received protection, food supplies were cut off and civilians were

encouraged not to join the uprising. Large numbers of people relocated to newly built, guarded camps.

Over several years, counterinsurgents restored order by degrees. This conflict illustrates Galula's point – disorder is easy to create and difficult to resolve. It took 40,000 counterinsurgents to defeat 8000 insurgents. It is believed that the most effective strategies used in Malaya were:

- Minimizing the deaths of noncombatant civilians and counterinsurgents.
- Building support from the population of Malaya, making them less likely to join the uprising.
- Enforcing an understanding that the insurgents were a risk to everyone.
- Creating organised political strategies and undermining those of insurgents.
- Reducing the incentives to rebel by providing Chinese citizens with fairer rights.
- Offering enticing sums of money to those who provided useful information and supported counterinsurgent efforts to locate insurgents.
- Giving insurgents the opportunity to surrender, without the risk of punishment. Although few actually opted for this, it created a sense of the government as trustworthy.

The Issues With Counterinsurgency

Counterinsurgency is never perfect and mistakes are always made. There are a number of key issues:

- Counterinsurgent efforts usually attempt to enforce Western attitudes and values. Most nations have a clear, although not always accurate, sense of their own equilibrium. Ignoring the importance of cultural relativism, counterinsurgents force round pegs into square holes. We think that our own way is the best, but who can decide what is best for a different country? Who says that modernization is the preferable route?
- Counterinsurgency is costly in terms of both human life and resources. In order to kill insurgents, civilian lives must be risked, while protecting civilians means more counterinsurgent casualties. Insurgents are often decentralised and spread out over large areas, meaning they have the advantage of surprise attack.
- Counterinsurgency is often ineffective. The solution for unrest is usually political changes, not military intervention. Combat alone cannot solve fundamental instability. There is also a lack of clear information as to the long term results. In some cases, it can backfire and worsen a situation.
- Counterinsurgency often lacks a clear end goal, or objectives may differ. The concepts of 'peace' and 'stability' are objective.

107. Activation Energy: Why Getting Started Is the Hardest Part

The beginning of any complex or challenging endeavor is always the hardest part. Not all of us wake up and jump out of bed ready for the day. Some of us, like me, need a little extra energy to transition out of sleep and into the day. Once I've had a cup of coffee, my energy level jumps and I'm good for the rest of the day. Chemical reactions work in much the same way. They need their coffee, too. We call this activation energy.

Understanding how this works can be a useful perspective as part of our latticework of mental models.

Whether you use chemistry in your everyday work or have tried your best not to think about it since school, the ideas behind activation energy are simple and useful outside of chemistry. Understanding the principle can, for example, help you get kids to eat their vegetables, motivate yourself and others, and overcome inertia.

How Activation Energy Works in Chemistry

Chemical reactions need a certain amount of energy to begin working. Activation energy is the minimum energy required to cause a reaction to occur.

To understand activation energy, we must first think about how a chemical reaction occurs. Anyone who has ever lit a fire will have an intuitive understanding of the process, even if they have not connected it to chemistry.

Most of us have a general feel for the heat necessary to start flames. We know that putting a single match to a large log will not be sufficient and a flame thrower would be excessive. We also know that damp or dense materials will require more heat than dry ones. The imprecise amount of energy we know we need to start a fire is representative of the activation energy.

For a reaction to occur, existing bonds must break and new ones form. A reaction will only proceed if the products are more stable than the reactants. In a fire, we convert carbon in the form of wood into CO₂ and is a more stable form of carbon than wood, so the reaction proceeds and in the process produces heat. In this example, the activation energy is the

initial heat required to get the fire started. Our effort and spent matches are representative of this.

We can think of activation energy as the barrier between the minima (smallest necessary values) of the reactants and products in a chemical reaction.

The Arrhenius Equation

Svante Arrhenius, a Swedish scientist, established the existence of activation energy in 1889.

Arrhenius developed his eponymous equation to describe the correlation between temperature and reaction rate.

The Arrhenius equation is crucial for calculating the rates of chemical reactions and, importantly, the quantity of energy necessary to start them.

In the Arrhenius equation, k is the reaction rate coefficient (the rate of reaction). A is the frequency factor (how often molecules collide), R is the universal gas constant (units of energy per temperature increment per mole), T represents the absolute temperature (usually measured in kelvins), and E is the activation energy.

It is not necessary to know the value of A to calculate E_a as this can be figured out from the variation in reaction rate coefficients in relation to temperature. Like many equations, it can be rearranged to calculate different values. The Arrhenius equation is used in many branches of chemistry.

Why Activation Energy Matters

Understanding the energy necessary for a reaction to occur gives us control over our surroundings.

Returning to the example of fire, our intuitive knowledge of activation energy keeps us safe. Many chemical reactions have high activation energy requirements, so they do not proceed without an additional input. We all know that a book on a desk is flammable, but will not combust without heat application. At room temperature, we need not see the book as a fire hazard. If we light a candle on the desk, we know to move the book away.

If chemical reactions did not have reliable activation energy requirements, we would live in a dangerous world.

Catalysts

Chemical reactions which require substantial amounts of energy can be difficult to control. Increasing temperature is not always a viable source of energy due to costs, safety issues, or simple impracticality. Chemical reactions that occur within our bodies, for example, cannot use high temperatures as a source of activation energy. Consequently, it is sometimes necessary to reduce the activation energy required.

Speeding up a reaction by lowering the activation energy required is called *catalysis*. This is done with an additional substance known as a catalyst, which is generally not consumed in the reaction. In principle, you only need a tiny amount of catalyst to cause catalysis.

Catalysts work by providing an alternative pathway with lower activation energy requirements. Consequently, more of the particles have sufficient energy to react.

Catalysts are used in industrial scale reactions to lower costs.

Returning to the fire example, we know that attempting to light a large log with a match is rarely effective. Adding some paper will provide an alternative pathway and serve as a catalyst — firestarters do the same.

Within our bodies, enzymes serve as catalysts in vital reactions (such as building DNA.)

“Energy can have two dimensions. One is motivated, going somewhere, a goal somewhere, this moment is only a means and the goal is going to be the dimension of activity, goal oriented-then everything is a means, somehow it has to be done and you have to reach the goal, then you will relax. But for this type of energy, the goal never comes because this type of energy goes on changing every present moment into a means for something else, into the future. The goal always remains on the horizon. You go on running, but the distance remains the same.”

No, there is another dimension of energy: that dimension is unmotivated celebration. The goal is here, now; the goal is not somewhere else. In fact, you are the goal. In fact, there is no other fulfillment than that of this moment—consider the lilies. When you are the goal and when the goal is not in the future, when there is nothing to be achieved, rather you are just celebrating it, then you have already achieved it, it is there. This is relaxation, unmotivated energy.”

— Osho, Tantra

Applying the Concept of Activation Energy to Our Daily Lives

Although activation energy is a scientific concept, we can use it as a practical mental model.

Returning to the morning coffee example, many of the things we do each day depend upon an initial push.

Take the example of a class of students set an essay for their coursework. Each student requires a different sort of activation energy for them to get started. For one student, it might be hearing their friend say she has already finished hers. For another, it might be blocking social media and turning off their phone. A different student might need a few cans of Red Bull and an impending deadline. Or, for another, reading an interesting article on the topic which provides a spark of inspiration. The act of writing an essay necessitates a certain sort of energy.

Getting kids to eat their vegetables can be a difficult process. In this case, incentives can act as a catalyst. “You can’t have your dessert until you eat your vegetables” is not only a psychological play on incentives; it also often requires less energy than constantly fighting with the kids to eat their vegetables. Once kids eat a carrot, they generally eat another one and another one. While they still want dessert, you won’t have to remind them each time, so you’ll save a lot of energy.

The concept of activation energy can also apply to making drastic life changes. Anyone who has ever done something dramatic and difficult (such as quitting an addiction, leaving an abusive relationship, quitting a long-term job, or making crucial lifestyle changes) knows that it is necessary to reach a breaking point first. The bigger and more challenging an action is, the more activation energy we require to do it.

Our coffee drinker might crave little activation energy (a cup or two) to begin their day if they are well rested. Meanwhile, it will take a whole lot more coffee for them to get going if they slept badly and have a dull day to get through.

Conclusion

To understand and use the concept of activation energy in our lives does not require a degree in chemistry. While the concept as used by scientists is complex, we can use the basic idea.

It is no coincidence that many of most useful mental models in our latticework originate from science. There is something quite poetic about the way in which human behavior mirrors what occurs at a microscopic level.

108. Human Misjudgment and the American Revolution

We try to look at mental models in history through the lens of people who got it right, but once in a while, it's beneficial to examine a model through the lens of those who got it wrong.

In this case, let's take a look at the remarkable series of misjudgments that resulted in the British losing their American colonies.

Our list of mental models includes 24 models in the human nature + judgment category, and at least seven of those were a factor in the British being driven out of America. Sometimes it helps to understand how great the consequences of these very human tendencies can be. And, perhaps more significantly, how a large group of people can succumb to them at the same time.

Bias from Incentives

Money, the root of stupidity.

In the mid-18th century, the British had a parliament, but it was very different from what exists today. As Barbara W. Tuchman describes in The March of Folly, the House of Commons was made up mostly of second sons of the nobility – the landowning class.

Urban centers such as London were poorly represented, and not surprisingly Parliament tended to pass laws that were primarily good for its members.

A lot of the issues which ultimately led to the revolution were about money.

The British wanted to tax the colonies, as Tuchman explains, so they would at least pay for their own defense, which was costly. The colonists felt that, with the exception of trade tariffs, the British had no right to tax those who were not represented in Parliament.

So part of the reason Parliament passed incendiary legislation, taxing, for example, stamps and tea, was so that the members of parliament, the landowners, could pay less tax. This was short-sighted — an incentive that could never be realized. As Tuchman describes, some more thoughtful dissenters pointed out that the cost of collecting the taxes from the hostile colonists was more than what the taxes would bring in.

Tendency to distort due to disliking/hating

We have written before that *“Our inability to examine the situation from all sides and shake our beliefs, together with self-justifying behavior, can lead us to conclude that others are the problem. Such asymmetric views, amplified by strong perceived differences, often fuel hate.”*

One of the things that Tuchman points out a few times is the complete ignorance of the British when it came to the sensibilities and interests of the Americans. And we can't blame this on the distance or comparative slow speed of communication. Tuchman highlights what is most startling is those in positions of power in the Parliament literally had no desire to understand the colonists' position. *“That the British were invincibly uninformed – and stayed uninformed – about the people they insisted on ruling was a major problem of the imperial-colonial relationship.”*

Parliament did not seek the advice or opinion of those Brits who had spent time in the colonies as Administrators, nor did it interview the well-educated and thoughtful Americans who were in London, such as Benjamin Franklin.

Due to their own sense of superiority, the British nobility believing they were the pinnacle of humanity, allowed their dislike of the colonists to distort the policies they pursued.

(Remember history doesn't repeat but it rhymes.) As Tuchman writes, *“Attitude was again the obstacle; the English could not visualize Americans in terms of equality.”*

You certainly don't declare war on people you admire and respect.

Denial Tendency

To stubbornly pursue a course of action in the face of evidence that it will eventually blow up in your face is denial. We all do it, but to do it as a political group can lose you a war.

The American revolution did not start without warning. There were years of attempts by the British to assert control over the colonies. As Tuchman describes, they would institute taxes then rescind them, only to reinstate them later. The colonists had the same response every time. They rejected the ability of the British to tax them. It was total denial that kept the British trying.

The British passed a series of acts, called the Coercive Acts that seemed designed to piss off the Americans. But in reality, it was more about the total inability of the British to see the situation clearly. Tuchman says, “if Britain had really been pursuing a plan to goad the colonies to insurrection in order to subjugate them, then her conduct of policy becomes rational. Unhappily for reason, that version cannot be reconciled to the repeals, the backings and fillings, the haphazard or individual decisions.”

As we mentioned earlier, the cost of bringing in the tax was more than the tax itself. And if taxation was the issue that was driving the colonies to war, then why keep doing it? Denial is likely part of the answer.

Social Proof

“When we feel uncertain, we all tend to look to others for answers as to how we should behave, what we should think and what we should do.”

This is social proof.

The House of Commons was not a homogenized unit; there were dissenters to the British approach in the American colonies, though these voices were always in the minority. Some people argued against the taxes and the war, offering alternatives to Parliament to act in the interest of keeping the colonies part of the empire. But the majority followed their peers.

Added to this was the fact that, as Tuchman describes, the situation in America wasn't a hot issue for most British. The nobility of the House of Commons was frequently more occupied with the various social scandals that occurred in their ranks.

What this helped to create was a situation of largely uninformed people responsible for voting on legislation that could have significant impacts. It is a human tendency to look to the majority for guidance on behavior when we are unsure about what to do. It is always easier to go with the majority than to oppose it. In the House of Commons, it was easier to vote with the majority than to take a stand against it, particularly if one wasn't all that interested in the issue.

First-Conclusion Bias

We tend to stick with the first conclusion we reach. Because of our commitment to our own narrative, it becomes very hard for us to change our minds once we form a definite opinion. This involves us admitting we made a mistake — something we avoid, as it can challenge our very sense of self.

The core issue that started the conflict between Britain and the American colonies, which eventually led to the war, was, as Tuchman describes, the absolute conviction of the British that they had a right to directly tax the colonies, and the equal conviction of the American that no right existed.

At the beginning, the Americans did attempt some compromise. The British, however, never did.

Despite the dissent, the cost, and the effects, the British never reexamined their first conclusion. It became layered with other issues but remained at the core of their position. Tuchman demonstrates that “they persisted in first pursuing, then fighting for an aim whose result would be harmful whether they won or lost.”

Their first conclusion, the right of the British state to tax the American colonies, was never abandoned or modified in light of what enforcing it would actually result in. Even if it were true, the absolute nature of their position prevented them from finding a compromise. This bias was a contributing factor in the result the British finally had to accept. The loss of the war.

Commitment and Consistency Bias

Partnered with the first conclusion bias, this one essentially reinforces the pain. This is what causes us to *“stick with our original decision, even in the face of new information.”*

Although consistency is generally perceived to be good, uncompromising consistency is more synonymous with ignorance and fear. If torpedos are aimed at your boat, your crew might appreciate you turning it around, giving yourself time to regroup.

The British made attempts to solve their problems, but these were halfhearted at best.

Tuchman actually depicts the British policy as not being consistent at all. The levied taxes, then they repealed them. They eventually sent a peace delegation but gave it no power to actually come to a compromise.

But they were fully committed to their overall attitude, which was, as Tuchman writes, *“a sense of superiority so dense as to be impenetrable. A feeling of this kind leads to ignorance of the world and of others because it suppresses curiosity. [All] ministries went through a full decade of mounting conflict with the colonies without any of them sending a representative, much less a minister, across the Atlantic to make acquaintance, to discuss, to find out what was spoiling, even endangering, the relationship and how it might be better managed. They were not interested in Americans because they considered them rabble or at best children whom it was inconceivable to treat – or even fight – as equals.”*

Given that this attitude of superiority was so entrenched, is it any wonder that the decisions made were those that reinforced this image?

Tendency to Want to Do Something

Busyness signals productivity. The faster you are walking the more important you are.

Having time on your hands means you aren't doing enough, not seizing the day, not contributing anything of value. Slow walkers are assumed to be seniors, students, or those who have nothing going on.

We can see the same trends in governments. Strong governments defend their position at all costs, while those who value negotiating or finding common ground are perceived as weaker. Powerful governments go to war. Those with less power find a compromise.

Tuchman claims, *“Confronted by menace, or what is perceived as menace, governments will usually attempt to smash it, rarely to examine it, understand it, define it.”*

So many times during the decade of conflict between the British and the Americans, the British might have put themselves in a better position if they had been willing to pause, regroup, or even walk away. Given some space, they might have compensated for the load of biases they were operating under and better defined and focused on a win-win solution.

But all the misjudgments flying around, combined with the innate human tendency to do something, led to chasing bad decisions with even worse ones.

[quote]If there is a silver lining, it's that we can learn from our mistakes so as to not be perpetual victims of our misjudgment tendencies.[/quote]

Tuchman concludes that the British did learn from their experiences during the American Revolution.

“Fifty years later, after a period of troubled relations with Canada, Commonwealth status began to emerge from the Durham Report, which resulted from England's recognition that any other course would lead to a repetition of the American rebellion.”

109. Active Listening: The Master Key to Effective Communication

"You cannot truly listen to anyone and do anything else at the same time."

— M. Scott Peck

The Basics

The sense that we are not being listened to is one of the most frustrating feelings imaginable. Toddlers scream about it, teenagers move out, couples split up, companies breakdown.

One of the main reasons this breakdown in communication occurs is that listening (like reading, thinking clearly and focusing) is a skill which we rarely consider to be something requiring knowledge and practice.

There is a difference between hearing and listening.

We assume that, as long as we can hear someone and understand their words that we are listening. Hearing alone, however, is not enough. Among other things, we need to comprehend what's being said and why, reflect on intentions, and consider non-verbal communication.

Listening is one of the foundations of society – it is what enables us to form meaningful relationships and connections. And yet most of us haven't thought about how we listen.

As Mortimer J. Adler writes in How to Speak, How to Listen:

We all realize that the ability to read requires training...the same would appear to be true of speaking and listening ... training is required ... Likewise, skill in listening is either a native gift or it must be acquired by training.

Active listening is a technique for developing our ability to listen.

As a communication technique, it is used in many professional settings but is also valuable for everyday life. Anyone who has ever seen a good therapist will be familiar with the efficacy of active listening. A one-to-one therapist will listen with intent, clarify any uncertain points, often paraphrase what is said and ask the speaker to expand. A family or couple therapist will help to resolve a conflict by facilitating calm communication through reflection, open body language, and by helping couples understand one another.

As Sheldon B. Kopp writes:

The therapist can interpret, advise, provide the emotional acceptance and support that nurtures personal growth, and above all, he can listen. I do not mean that he can simply hear the other, but that he will listen actively and purposefully, responding with the instrument of his trade that is, with the personal vulnerability of his own trembling self. This listening is that which will facilitate the patient's telling of his tale, the telling that can set him free.

For the sake of clarity, we will refer to active listening in the context of two people conversing throughout this article. However, it can occur in communication between multiple people and in groups.

[quote]Listening is difficult because it involves suppressing your ego long enough to consider what is being said before you respond.[/quote]

The Core Components of Active Listening

Comprehending

To communicate, we must first understand what the other person (or people) are actually saying. This is not as simple as it appears.

In most cases, comprehension occurs instantly and unconsciously. However, a number of potential barriers can prevent comprehension, including:

- Language barriers.
- The use of jargon or slang.
- Difference in culture, age, social rank and other discrepancies between people.

In Eyes Wide Open, Isaac Lidsky recommends simplifying comprehension by asking 'can you explain that like I'm five years old?.' This is the same technique we use to rapidly improve learning. Removing jargon and explaining things in your own language results in massively improved comprehension of complex topics.

Retaining

To respond in an appropriate manner, we must understand and retain what the other person has said. Not everyone will retain the same details.

Some people recall very specific details, while others hold on to the general idea. It is common for us to only retain details which are relevant for our response.

When actively listening, we focus on the other person's words, rather than thinking about what we can say next. Suppressing our ego is difficult. It's as if we think we already know what the other person is going to say. And we fool ourselves into thinking that we've done the work: that we not only know what the other person will say but that we've thought about it before. Only, we haven't.

There are a number of potential barriers to retention, including:

- Cognitive biases and selective listening (we will look at this in more detail later.)
- Distractions, either internal or external (such as fatigue or a noisy environment.)
- Issues with memory (such as Dementia.)

Responding

Conversations are active, not passive. A conversation between people cannot occur without a response.

Active listening requires careful responses which are made possible with comprehending and retaining.

An active response should show that we understand what the other person has said, have paid attention to their words and also read their non-verbal cues.

Ronald A. Heifetz writes that "The activity of interpreting might be understood as listening for the song beneath the words." To be an active listener, we must try to go beyond the words and form a rich picture of the other person's emotions and intentions. However, we must also avoid inventing meaning or colouring their words with our own thoughts. The same potential barriers apply to responding as to retaining and comprehending.

[quote]To be an active listener, we must try to go beyond the words and form a rich picture of the other person's emotions and intentions.[/quote]

Active Listening and Overcoming Cognitive Biases

Active listening requires an understanding of how cognitive biases and shortcuts impact our communication. These are particularly prevalent when people are arguing and disagreeing.

Consider the following hypothetical argument between a couple, Mary and John. Any resemblance to your marriage is purely coincidental.

Mary: You never help around the house, you came home drunk twice last week, you forgot to pick the kids up from school, you never buy me flowers, you—

John: I bought you flowers on Valentine's day!

In this instance, John is succumbing to confirmation bias in order to refute Mary's statements. Ignoring the other claims, he responds to the one which he can easily disagree with. John fools himself into believing that because he can refute one statement, they are all false.

John: I bought you flowers on Valentine's day!

Mary: That was the first you've brought me flowers in 5 years.

John is now falling prey to availability bias. He remembers one event which was recent and salient, *while ignoring the preceding times*.

Mary: That was the first time you've brought me flowers in 5 years.

John: So? None of my friends buy their partners flowers, even on Valentine's day.

Social proof is now coming into play. John has looked to their peers for clues as to how he should behave. Rather than considering how Mary feels, he is reassuring himself that his behavior is fine because it is common.

Mary: Anyway, the flowers you brought me that time were wilted and you clearly got them from the gas station on your way home.

Here, Mary is seeing a distorted view of events due to her current anger (bias from hating/disliking.) An event which previously made Mary happy is now only further evidence of her partner's inadequacy.

The examples above are just a few of the numerous cognitive biases and shortcuts which impede our communication.

Now, let's imagine how this argument might have gone if John had used active listening techniques.

This would necessitate putting aside emotions and ego and rather trying to understand why Mary is upset.

Mary: You never help around the house, you came home drunk twice last week, you forgot to pick the kids up from school, you never buy me flowers and I'm sick of it.

John: So, you feel I am being a bad parent, ignoring your needs, and allowing my social life to interfere with our relationship?

John is now paraphrasing what Mary has said, confirming that he is listening. It's important to note that John is not outright agreeing with Mary. Rather than seeking to defend himself, he is making sure Mary knows he is listening.

By keeping calm and showing open body language, he can then allow Mary to finish venting her frustration without interrupting. This provides a safe and secure environment for Mary to open up and express her true feelings.

John maintains eye contact and uses nonverbal cues (such as nodding and tilting his head to indicate he is listening.) Mary relaxes a little, seeing that her partner appears to be truly interested in what she has to say.

Then, John can speak:

John: What can I do which would make you feel better about our relationship?

This question is neutral and not related to personal opinion. John has allowed Mary to explore her feelings. By continuing in this way, they can turn an argument into a valuable opportunity to understand each other better.

The result in this situation is likely to be far more positive than the initial example. Even just by reading the words, you probably pictured both scenarios somewhat differently, complete with altered tones of voice and outcomes.

Active Listening as a Means of Overcoming Conversational Narcissism

If you have ever been in a conversation with someone who is only interested in talking about themselves, you will understand what conversational narcissism is and how it makes you feel.

Sociologist Charles Derber first observed the phenomenon, wherein people allow their self obsession to manifest in their conversational practices. Rather than listening to what the other person has to say and responding accordingly, many people shift the discussion to themselves.

In Inarticulate Society: Eloquence and Culture in America, Tom Shachtman writes:

[Conversational Narcissism] is pervasive and rooted in our culture of individualism, a pattern that leads to self-absorption ... by the use of 'I' statements, by boasting, by the tactic of asking questions only in order to demonstrate the questioner's superior knowledge or to top the other person's story with one's own, and by continual shifting... The most frequently used written word in the language is 'the', but the most frequently spoken word..is 'I.'

Derber describes this as the 'shift response' as opposed to a 'support response.' In The Pursuit of Attention: Power and Ego in Everyday Life, he writes:

The subtlety of the shift-response is that it is always based on a connection to the previous subject. This creates an opening for the respondent to shift the topic to himself ... when serving narcissistic ends, shift-responses are repeated until a clear shift in subject has transpired ... The effectiveness is the shift response as an attention getting device lies partly in the difficulty in distinguishing immediately whether a given response is a sharing one of a narcissistic initiative.

Conversational narcissists will often repeat shift-responses until the conversation steers towards them. Again.

Returning to our hypothetical couple, this might look like this:

John: I'm just really stressed about work at the moment.

Mary: Me too, you wouldn't believe what one of my coworkers did yesterday.

John: And it's hard for me to pay enough attention to the kids when I have this much on my plate and just want to relax when I get home.

Mary: Seriously, what she did was ridiculous.

John: What did she do?

In this conversation, Mary repeats the shift-response until John finally gets the point and switches the topic away from himself.

The narcissistic nature of this is obvious in a conversational transcript but can be difficult to identify.

Support-responses are the opposite of shift-responses — they sustain the speaker's words and encourage them. If Mary had used support responses, the conversation might look like this:

John: I'm just really stressed about work at the moment.

Mary: Why is it more stressful than usual right now?

John: Well, one of the people in my team is on holiday for a couple of weeks and I keep getting landed with their usual responsibilities.

Mary: Have you spoken to your boss about that? You shouldn't be doing someone else's job as well as your own.

Notice how different those two scenarios sounded in your head.

In the first conversation, Mary was purely narcissistic and just wanted to talk about herself.

In the second, the couple was able to understand each other a bit better and to see a potential root cause of their conflict.

Conversational narcissism also occurs through passive behavior.

Derber writes:

Passive conversational narcissism entails neglect of supportive questions at all such discretionary points and extremely sparse use of them throughout conversation. Listening behaviour takes place but is passive. There is little attempt to draw others out or assume other forms of active listening. This creates doubt in the other regarding the interest of their topics or their rights to attention ... A second very common minimal use practice involves the ... delay of background acknowledgements. Although weaker than supportive questions, background acknowledgements such as 'yeah' or 'uh huh' are nonetheless critical cues by which speakers gauge the degree of interest in their topics.

As Derber illustrates, we must not underestimate the importance of our responses when it comes to active listening.

The other person does not care if we listen with great attention if our responses do not reflect this. In some cases, a comment or question is necessary. Often, a simple acknowledgment is sufficient.

In The Plateau Effect, Sullivan and Thompson explain the folly of conversational narcissism:

Most people listen with intent to do something – usually to defend themselves, or to solve a problem. Nearly everyone listens with the intent of having something ready to say as soon as the speaker is finished. Have you ever wondered how crazy that is? Shouldn't there be a pause once in a while, as one of the speakers actually thinks about what to say, or even better, thinks about what has been said? Here's a phenomenon you'll observe repeatedly if you look for it: Two speakers, appearing to be carrying on a conversation, but really just giving two monologues, split up by each other, each one waiting simply for time on whatever stage he or she imagines to be on...Listeners usually can't wait to leap to their own defense, and spend their time thinking like an attorney who's planning a closing argument rather than hearing what's being said. You can imagine how ineffective this is."

How Can We Improve Our Active Listening Skills?

While there is no one method for learning to listen actively, there are a number of small changes we can make.

Active listening, like any skill, is developed by practicing, not by reading about it. By applying the concept to each conversation we have, we can gradually develop the ability to communicate well. This might include:

- Educate yourself on common cognitive biases and shortcuts. Learn to spot them in yourself and others and to see how they impede communication.
- Avoid trying to respond immediately. Allow the other person time to finish speaking, then provide a considered response. Consider first if it is a shift or support response.
- Minimize conversational narcissism by keeping track of your use of pronouns. An over-reliance on 'I' and 'me' can indicate a desire to steer the conversation towards yourself. Aim to make liberal use of 'you' instead.
- Adler recommends taking notes during key conversations. Although this may be disconcerting to a speaker, it is relevant in some situations. Adler writes: *"The notes you take while listening record what you have done with your mind to take in what you have heard. That record enables you to go on to the second step...What you have notes...provides you with food for thought."*
- During an argument, accept that people are rarely willing to change their viewpoint. Instead of becoming enraged or frustrated, seek to develop a clear picture of the other person's logic. Using the Socratic questioning technique can be helpful for drawing out this information. Using active listening, it is possible to turn an argument into a calm discussion, where you can explain your own thoughts. Adler explains: *"The logically sensitive speaker will ask you to follow his reasoning by accepting his assumptions for the time being – accepting them to discern their consequences, to see how they lead to the conclusions he wishes to arrive at...they are not axioms or self-evident truths...your task is to be on the alert to detect the initial premises...that provide the ultimate grounds for what is being said."*
- Increase your motivation to listen. This is known as the affective framework for active listening. This motivation might be the desire to improve a relationship, follow instructions without wasting time, make someone feel better or to make an exchange as clear as possible.

110. The Trojan Horse: When True Intents Are Concealed

A Trojan Horse is an innocuous appearing container for hiding something within to get past defenses or some other obstacle. Trojan Horses can be used for both good and evil. Here's how to recognize and use them.

The Basics

The story of the Trojan Horse is perhaps the most famous of all the Greek myths.

The Trojan War had been going on for a decade, with no end in sight and many Greek heroes dying, when Odysseus came up with an idea that won the war for the Greeks. Because the Trojans considered horses to be sacred, the Greeks built a large, hollow wooden horse. To make it even more irresistible, they used wood from Cornel trees (also sacred) to construct it. Odysseus and a group of men hid inside while the rest of the Greek army pretended to leave the area, destroying their camp and boarding their ships. After some debate as to whether the Greeks could be trusted, the Trojans dragged the giant horse inside the walls of the city. The end of the ten-year siege was a huge relief to the people of Troy, who spent the night celebrating.

By midnight, everyone was in a drunken stupor. Odysseus then acted, signaling to the Greek fleet to return and leading his men out of the Trojan Horse to kill the unsuspecting guards and open the doors. The Greeks then had access to the city. They massacred the Trojans, keeping a few alive as slaves. Some of the soldiers traveled further afield, forming settlements which are supposed to have led to the creation of Rome.

Ancient Greeks saw this myth as factual, with the events occurring between 1300–1200 BC in the area near Dardanelles.

There is some archeological evidence for the existence of Troy, although most historians now accept that the story is mythological. There is probably still some basis in actual events, as sieges were common during that era.

Myth or not, the fact that the story of the Trojan Horse has survived for over 3,000 years indicates its power and utility as a mental model.

Why, exactly, has this particular story retained its grip on our imagination for so long?

We can only speculate as to why. Perhaps the answer lies in the fact that the Trojan Horse is not just a story. It's also a parable, a metaphor, an invitation to be ingenious, an example of out-of-the-box thinking.

Reading it has sparked so many ideas for so many people. It is at once practical and bizarre.

Using it as a mental model, we can apply the Trojan Horse story to an array of disciplines and situations. As a concept, it can be used for both good and evil.

The Trojan Horse in Marketing and Business

We live in an era when we are all besieged by marketing messages every moment of the day. Like the Trojans hiding in their city, we have learned to shut these messages out — we use advertisement blockers, throw away junk mail unopened, ignore billboards, and filter out spam emails.

In order to gain our attention, marketers often use a technique similar to the Trojan Horse. They offer people an apparent gift — a free ebook, a discount card, a sample. Only once this item has been enjoyed can its real purpose can be enacted.

[quote]A good heuristic when things seem too good to be true is to just forget about them.[/quote]

Many marketing lessons can be found in the original myth.

The Greeks chose a form which appealed to their targets, using a sacred creature and type of wood. Likewise, marketers must fit their gift to the audience, making it appealing to their basic interests. The Greeks used innovative thinking, inventing a tactic which was

new and therefore unexpected. If they had tried the same thing again, it would have had no effect.

Once a marketing technique is recognizable, its impact wanes. No one is going to click on a “5 ways to kill belly fat” pop-up anymore, or fall for an email from a Nigerian prince telling you just how much money you left there, or enjoy a free executable file that will clean your computer. These ruses are now well known and we ignore them. But when these techniques were new and unfamiliar, huge numbers of people were attracted by the offers.

Some examples of Trojan Horse marketing include:

- Offering the first chapter of a book for free to people who join an email list — Having read the chapter and received more emails which connect them to the author, people are more likely to buy the full book than they would have been if they had only seen an advert.
- Creating free high-quality blog content for an audience to enjoy — Once people are interested in the blogger’s voice and expertise, the marketing can begin. Many people will at some point want to support the person whose work they have been consuming for free. This support might include buying courses, books, or consulting services or donating to a Patreon page. We developed the membership as not only a bunch of extras for people but also a means to support the free content we provide.
- Writing a book detailing an expert’s specialized knowledge — While sales of the book are often not high, having it published benefits the expert’s business. For example, Ryan Holiday has stated that his books have led to more income from speaking and consulting than from actual book sales.
- Making the most income from revenue streams which do not appear to be the main objective of a business — For example, high-fashion brands often make more money from perfume than from clothing, cinemas rely on sales of popcorn and drinks, and some restaurants profit predominantly from sales of alcohol.
- Creating viral branded content which people share and engage with due to its being interesting and often amusing — For example, just try to watch the Android “Friends Furever” video without forwarding it to at least one person. The adorable video wraps up a marketing message, making people more likely to pay attention to it.

In his book *Permission Marketing*, Seth Godin discusses the idea under a different name. When you let people into your inbox, you’re letting people into your city. They might be there for good or bad reasons; it’s hard to know in advance. In a blog post, Godin explains how the concept works:

Permission marketing is the privilege (not the right) of delivering anticipated, personal, and relevant messages to people who actually want to get them.

It recognizes the new power of the best consumers to ignore marketing. It realizes that treating people with respect is the best way to earn their attention.

Pay attention is a key phrase here, because permission marketers understand that when someone chooses to pay attention they are actually paying you with something precious...

Real permission works like this: if you stop showing up, people complain, they ask where you went...

Permission is like dating. You do not start by asking for the sale at first impression. You earn the right, over time, bit by bit...

In order to get permission, you make a promise. You say, “I will do x, y and z, I hope you will give me permission by listening.” And then, this is the hard part, that’s all you do. You

do not assume you can do more. You do not sell the list or rent the list or demand more attention...

In the book, Godin explains how Amazon has used permission marketing to build an empire:

Using permission, Amazon can fundamentally reconfigure the entire book industry, disintermediating and combining every step of the chain until there are only two: the writer and Amazon ... Amazon appears to be building a permission asset, not a brand asset.

Amazon began by offering cheap books. Once people fell for that initial Trojan Horse, Amazon offered them other products and gradually captured more and more of their online spending. Services such as Prime, Echo, and Kindle are contained within the Trojan Horse — that first cheap purchase someone makes.

Just as the Greeks invested effort into building the horse, Amazon has invested millions in technology and infrastructure. This is the essence of Trojan Horse marketing: offering a gift (with Amazon, this includes free trials, discounts, and generally low costs for popular items) and then upselling and upselling and upselling.

On the topic of Amazon Prime, John Warrillow writes:

Like many subscription models, Amazon Prime is a Trojan horse that is expanding the list of products consumers are willing to buy from Amazon and giving the eggheads in Seattle a mountain of customer data to sift through.

The Trojan Horse and the Benjamin Franklin Effect

Let's say there is a person who dislikes you — a lot. It's fine; this happens to all of us. But what if you need to form an allegiance with this person? Or maybe they don't dislike you, they just don't know you. Either way, you need to build a relationship with them. What should you do? Ask them out for coffee, offer a gift, ask someone for an email introduction?

One solution is to utilize the Benjamin Franklin effect, essentially a sort of Trojan Horse approach to building relationships.

The Benjamin Franklin effect is a psychological phenomenon in which we begin to like people we have done favors for. Essentially, the initial favor is the Trojan Horse, containing within it a relationship. Franklin's original story, told in his autobiography, details how he used this during his time as a legislator:

Having heard that he [a rival who disliked Franklin] had in his library a certain very scarce and curious book, I wrote a note to him, expressing my desire of perusing that book, and requesting he would do me the favour of lending it to me for a few days. He sent it immediately, and I return'd it in about a week with another note, expressing strongly my sense of the favour.

When we next met in the House, he spoke to me (which he had never done before), and with great civility; and he ever after manifested a readiness to serve me on all occasions, so that we became great friends, and our friendship continued to his death.

We can use Franklin's technique as a Trojan Horse to gain the respect, friendship, and cooperation of other people.

Asking someone for a favor indicates that we already respect them and consider them to have something we lack — a form of flattery which serves as the gift. Once they have accepted this and performed the favor, it can be leveraged.

Examples of the conjunction between the Benjamin Franklin effect and the Trojan Horse include:

- Salesmen use the foot-in-the-door technique. This involves making a small request (for example, filling in a survey), then trying to sell you something.
- If someone you know has a particular area of expertise, try texting or emailing them (rather than Googling it) whenever you have a related question. One Reddit user on r/LifeProTips recommends texting your mother simple questions on a regular basis

to strengthen the relationship. Doing so indicates to people that we consider them knowledgeable, making them more likely to respond to larger requests.

Robert Greene also recommends a number of Trojan Horse—style tactics in *The 48 Laws of Power*, concealing true intentions within a facade and using specific behavior to achieve goals.

Use selective honesty and judgment to disarm ... One sincere and honest move will cover over dozens of dishonest ones. Open-hearted gestures of honesty and generosity bring down the guard of even the most suspicious people. Once your selective honesty opens a hole in their armor, you can deceive and manipulate them at will. A timely gift—a Trojan horse—will serve the same purpose.

In *The 33 Strategies of War*, Greene returns to the same analogy:

[B]efriend your enemies, worming your way into their hearts and minds. As your targets' friend, you will naturally learn their needs and insecurities, the soft interior they try so hard to hide. The guard will come down with a friend. And even later on, when you play out your treacherous intentions, the lingering resonance of your friendship will still confuse them, letting you keep on manipulating them by toying with their emotions or pushing them into overreactions. For a more immediate effect, you can try a sudden act of kindness and generosity that gets people to lower their defenses—the Trojan Horse strategy. ...

When confronted by something difficult or thorny, do not be distracted or discouraged by its formidable outer appearance; think your way into the soft core, the center from which the problem blossoms... Knowing the problem's core gives you great power to change it from the inside out. Your first thought must always be to infiltrate the center... never to whale away at the periphery or just pound at the walls.

How Artists Change Your Mind

Many artists (a term used here to denote anyone who creates something, not just those who paint canvases) have used their work to conceal important agendas.

The Beatles, Bob Dylan, and Conor Oberst wrap political and social messages within beautiful music.

Bloggers such as Seth Godin and James Altucher envelop key life lessons and paradigm-altering concepts within humorous anecdotes and metaphors. The women who embroidered the Bayeux Tapestry added their own subtle views to the panoramas of war and victory.

Companies such as Toms, Ben & Jerry, and Lush use the popularity of their products to fund real change. Johannes Vermeer's most serene paintings tell complex, taboo narratives.

Botticelli's La Primavera (above) is actually an exploration of his interest in horticulture, not a study of human figures.

Consider Gatsby, throwing lavish parties with the sole purpose of attracting Daisy back to him. This is the essence of much of art — an attractive and appealing exterior conceals the true purpose.

People use whatever means are available to them to express their views and attitudes. Sometimes this is intentional; sometimes the Trojan Horse is built unconsciously. The purpose is to get a message across in a form which is palatable to people.

Few of us enjoy or engage with straightforward expressions of a particular agenda. But when it comes in an interesting form, we pull the wooden horse within the city walls with glee. Just as with marketing messages, we have become desensitized to these sorts of messages. Artists must now use ingenuity and creativity to spread their ideas.

As Walter Hamady writes:

The book as a structure is the Trojan horse of art — it is not feared by average people. It is a familiar form in the world, and average people will take it from you and examine it whereas a painting, poem, sculpture, or print they will not.

This concept of art as a Trojan Horse is extremely important.

Farnam Street itself serves as a Trojan Horse. Our intention is to spread an appreciation of the importance of clear thinking, lifelong learning, making good decisions and living a meaningful life.

If upon your first visit to this site, you had found nothing but a list of instructions, the chances are high that you would have ignored it and never returned. Through the use of stories, analogies and careful explorations of important ideas, this agenda has reached and inspired many people. When you read a post about a military tactic or the life of a historic figure, the purpose is not the narrative alone. It is about much more than that — a way of changing how people think.

In *Contagious*, Jonah Berger explains the power of stories as a Trojan Horse:

People don't just share information, they tell stories. But just like the epic tale of the Trojan Horse, stories are vessels that carry things such as morals and lessons. Information travels under the guise of what seems like idle chatter. So, we need to build our own Trojan horses, embedding our products and ideas in stories that people want to tell... we need to make our message so integral to the narrative that people can't tell the story without it.

Francis T. Marchese also advocates the Trojan Horse approach to art:

The Trojan Horse is an artifact that possesses a host of hidden agendas. Rather than presenting a one-off manifestation, the Trojan Horse offers many platoons, capable of strategically addressing the wider culture, pointing to replicable solutions through demonstration. Thus, an artwork acting like a Trojan Horse can contain the seeds of multiple strategic outcomes.

In short, when we want to spread an idea or spark change, we would do well to learn from the ancient Greeks.

People have strong defenses against anything which challenges their worldviews. By packaging it in a format which appeals to them, we can pass on meaning. Artists, marketers, and politicians (among others) have long realized the importance of this approach. It is a means of injecting our ideas, both good and bad, into people's worlds through an apparent gift.

111. Critical Mass and Tipping Points: How To Identify Inflection Points Before They Happen

Critical mass, which is sometimes referred to as tipping points, is one of the most effective mental models you can use to understand the world. The concept can explain everything from viral cat videos to why changing habits is so hard.

The Basics

Sometimes it can seem as if drastic changes happen at random.

One moment a country is stable; the next, a revolution begins and the government is overthrown. One day a new piece of technology is a novelty; the next, everyone has it and we cannot imagine life without it. Or an idea lingers at the fringes of society before it suddenly becomes mainstream.

As erratic and unpredictable as these occurrences are, there is a logic to them, which can be explained by the concept of critical mass. A collaboration between Thomas Schelling (a game theorist) and Mark Granovetter (a sociologist) led to the concept's being identified in 1971.

Also known as the boiling point, the percolation threshold, the tipping point, and a host of other names, critical mass is the point at which something (an idea, belief, trend, virus, behavior, etc.) is prevalent enough to grow, or sustain, a process, reaction, or technology. As a mental model, critical mass can help us to understand the world around us by letting us spot changes before they occur, make sense of tumultuous times, and even gain insight into our own behaviors. A firm understanding can also give us an edge in launching products, changing habits, and choosing investments.

In *The Decision Book*, Mikael Krogerus wrote of technological critical masses:

Why is it that some ideas – including stupid ones – take hold and become trends, while others bloom briefly before withering and disappearing from the public eye?

... Translated into a graph, this development takes the form of a curve typical of the progress of an epidemic. It rises, gradually at first, then reaches the critical point of any newly launched product, when many products fail. The critical point for any innovation is the transition from the early adapters to the sceptics, for at this point there is a 'chasm'. ... With technological innovations like the iPod or the iPhone, the cycle described above is very short. Interestingly, the early adaptors turn away from the product as soon as the critical masses have accepted it, in search of the next new thing.

In *Developmental Evaluation*, Michael Quinn Patton wrote:

Complexity theory shows that great changes can emerge from small actions. Change involves a belief in the possible, even the "impossible." Moreover, social innovators don't follow a linear pathway of change; there are ups and downs, roller-coaster rides along cascades of dynamic interactions, unexpected and unanticipated divergences, tipping points and critical mass momentum shifts. Indeed, things often get worse before they get better as systems change creates resistance to and pushback against the new.

In *If Nobody Speaks of Remarkable Things*, Jon McGregor writes a beautiful explanation of how the concept of critical mass applies to weather:

He wonders how so much water can resist the pull of so much gravity for the time it takes such pregnant clouds to form, he wonders about the moment the rain begins, the turn from forming to falling, that slight silent pause in the physics of the sky as the critical mass is reached, the hesitation before the first swollen drop hurtles fatly and effortlessly to the ground.

Critical Mass in Physics

In nuclear physics, critical mass is defined as the minimum amount of a fissile material required to create a self-sustaining fission reaction. In simpler terms, it's the amount of reactant necessary for something to happen and to keep happening.

This concept is similar to the mental model of activation energy. The exact critical mass depends on the nuclear properties of a material, its density, its shape, and other factors. In some nuclear reactions, a reflector made of beryllium is used to speed up the process of reaching critical mass. If the amount of fissile material is inadequate, it is referred to as a subcritical mass. Once the rate of reaction is increasing, the amount of material is referred to as a supercritical mass. This concept has been taken from physics and used in many other disciplines.

Critical Mass in Sociology

In sociology, a critical mass is a term for a group of people who make a drastic change, altering their behavior, opinions or actions.

“When enough people (a critical mass) think about and truly consider the plausibility of a concept, it becomes reality.”

—Joseph Duda

In some societies (e.g., a small Amazonian tribe), just a handful of people can change prevailing views. In larger societies (in particular, those which have a great deal of control over people, such as North Korea), the figure must usually be higher for a change to occur. The concept of a sociological critical mass was first used in the 1960s by Morton Grodzins, a political science professor at the University of Chicago. Grodzins studied racial segregation — in particular, examining why people seemed to separate themselves by race even when that separation was not enforced by law. His hypothesis was that white families had different levels of tolerance for the number of people of racial minorities in their neighborhoods. Some white families were completely racist; others were not concerned with the race of their neighbors. As increasing numbers of racial minorities moved into neighborhoods, the most racist people would soon leave. Then a tipping point would occur — a critical mass of white people would leave until the area was populated by racial minorities. This phenomenon became known as “white flight.”

Critical Mass in Business

In business, at a macro level, critical mass can be defined as the time when a company becomes self-sustaining and is economically viable. (Please note that there is a difference between being economically viable and being profitable.) Just as a nuclear reaction reaches critical mass when it can sustain itself, so must a business. It is important, too, that a business chooses its methods for growth with care: sometimes adding more staff, locations, equipment, stock, or other assets can be the right choice; at other times, these additions can lead to negative cash flow.

The exact threshold and time to reach critical mass varies widely, depending on the industry, competition, startup costs, products, and other economic factors.

Bob Brinker, host of Money Talk, defines critical mass in business as:

A state of freedom from worry and anxiety about money due to the accumulation of assets which make it possible to live your life as you choose without working if you prefer not to work or just working because you enjoy your work but don't need the income. Plainly stated, the Land of Critical Mass is a place in which individuals enjoy their own personal financial nirvana. Differentiation between earned income and assets is a fundamental lesson to learn when thinking in terms of critical mass. Earned income does not produce critical mass ... critical mass is strictly a function of assets.

Independence or “F*** You” Money

Most people work jobs and get paychecks. If you depend on a paycheck, like most of us, this means you are not independent — you are not self-sustaining. Once you have enough money, you can be self-sustaining.

If you were wealthy enough to be free, would you really keep the job you have now? How many of us check our opinions or thoughts before voicing them because we know they

won't be acceptable? How many times have you agreed to work on a project that you know is doomed, because you need the paycheck?

"Whose bread I eat: his song I sing."

—Proverb

In his book *The Black Swan*, Nassim Taleb describes "f*** you" money, which, "in spite of its coarseness, means that it allows you to act like a Victorian gentleman, free from slavery":

*It is a psychological buffer: the capital is not so large as to make you spoiled-rich, but large enough to give you the freedom to choose a new occupation without excessive consideration of the financial rewards. It shields you from prostituting your mind and frees you from outside authority — any outside authority. ... Note that the designation f*** you corresponds to the exhilarating ability to pronounce that compact phrase before hanging up the phone.*

Critical Mass in Psychology

Psychologists have known for a long time that groups of people behave differently than individuals.

Sometimes when we are in a group, we tend to be less inhibited, more rebellious, and more confident. This effect is known as mob behavior. (An interesting detail is that mob psychology is one of the few branches of psychology which does not concern individuals.)

As a general rule, the larger the crowd, the less responsibility people have for their behavior. (This is also why individuals and not groups should make decisions.)

"[Groups of people] can be considered to possess agential capabilities: to think, judge, decide, act, reform; to conceptualize self and others as well as self's actions and interactions; and to reflect."

—Burns and Engdahl

Gustav Le Bon is one psychologist who looked at the formation of critical masses of people necessary to spark change. According to Le Bon, this formation creates a collective unconsciousness, making people "a grain of sand amid other grains of sand which the wind stirs up at will."

He identified three key processes which create a critical mass of people: anonymity, contagion, and suggestibility. When all three are present, a group loses their sense of self-restraint and behaves in a manner he considered to be more primitive than usual. The strongest members (often those who first convinced others to adopt their ideas) have power over others.

Examples of Critical Mass

Virality

Viral media include forms of content (such as text, images, and videos) which are passed amongst people and often modified along the way. We are all familiar with how memes, videos and jokes spread on social media. The term "virality" comes from the similarity to how viruses propagate.

"We are all susceptible to the pull of viral ideas. Like mass hysteria. Or a tune that gets into your head that you keep on humming all day until you spread it to someone else. Jokes. Urban legends. Crackpot religions. No matter how smart we get, there is always this deep irrational part that makes us potential hosts for self-replicating information."

—Neal Stephenson, *Snow Crash*

In *The Selfish Gene*, Richard Dawkins compared memes to human genes. While the term “meme” is now, for the most part, used to describe content that is shared on social media, Dawkins described religion and other cultural objects as memes.

The difference between viral and mainstream media is that the former is more interactive and is shaped by the people who consume it. Gatekeeping and censorship are also less prevalent. Viral content often reflects dominant values and interests, such as kindness (for example, the dancing-man video) and humor. The importance of this form of media is apparent when it is used to negatively impact corporations or powerful individuals (such as the recent United Airlines and Pepsi fiascoes.)

Once a critical mass of people share and comment on a piece of content online, it reaches viral status. Its popularity then grows exponentially before it fades away a short time later. Technology

The concept of critical mass is crucial when it comes to the adoption of new technology. Every piece of technology which is now (or once was) a ubiquitous part of our lives was once new and novel.

Most forms of technology become more useful as more people adopt them. There is no point in having a telephone if it cannot be used to call other people. There is no point in having an email account if it cannot be used to email other people.

The value of networked technology increases as the size of the network itself does. Eventually, the number of users reaches critical mass, and not owning that particular technology becomes a hindrance. Useful technology tends to lead the first adopters to persuade those around them to try it, too. As a general rule, the more a new technology depends upon a network of users, the faster it will reach critical mass. This situation creates a positive feedback loop.

In *Zero to One*, Peter Thiel describes how PayPal achieved the critical mass of users needed for it to be useful:

For PayPal to work, we needed to attract a critical mass of at least a million users.

Advertising was too ineffective to justify the cost. Prospective deals with big banks kept falling through. So we decided to pay people to sign up.

We gave new customers \$10 for joining, and we gave them \$10 more every time they referred a friend. This got us hundreds of thousands of new customers and an exponential growth rate.

Another illustration of the importance of critical mass for technology (and the unique benefits of crowdfunding) comes from Chris LoPresti:

A friend of mine raised a lot of money to launch a mobile app; however, his app was trounced by one from another company that had raised a tenth of what he had, but had done so through 1,000 angels on Kickstarter. Those thousand angels became the customers and evangelists that provided the all-important critical mass early on. Any future project I do, I'll do through Kickstarter, even if I don't need the money.

Urban Legends

Urban legends are an omnipresent part of society, a modern evolution of traditional folklore. They tend to involve references to deep human fears and popular culture.

Whereas traditional folklore was often full of fantastical elements, modern urban legends are usually a twist on reality. They are intended to be believed and passed on. Sociologists refer to them as “contemporary legends.” Some can survive for decades, being modified as time goes by and spreading to different areas and groups. Researchers who study urban legends have noted that many do have vague roots in actual events, and are just more sensationalized than the reality.

One classic urban legend is “The Hook.” This story has two key elements: a young couple parked in a secluded area and a killer with a hook for a hand. The radio in their car announces a serial killer on the loose, often escaped from a nearby institution, with a hook for a hand. In most versions, the couple panics and drives off, only to later find a hook

hanging from the car door handle. In others, the man leaves the car while the woman listens to the radio bulletin. She keeps hearing a thumping sound on the roof of the car. When she exits to investigate, the killer is sitting on the roof, holding the man's severed head. The origins of this story are unknown, although it first emerged in the 1950s in America. By 1960, it began to appear in publications.

Urban legends are an example of how a critical mass of people must be reached before an idea can spread. While the exact origins are rarely clear, it is assumed that it begins with a single person who misunderstands a news story or invents one and passes it on to others, perhaps at a party.

Many urban legends have a cautionary element, so they may first be told in an attempt to protect someone. "The Hook" has been interpreted as a warning to teenagers engaging in promiscuous behavior. When this story is looked at by Freudian folklorists, the implications seem obvious. It could even have been told by parents to their children.

This cautionary element is clear in one of the first printed versions of "The Hook" in 1960: *If you are interested in teenagers, you will print this story. I do not know whether it's true or not, but it does not matter because it served its purpose for me... I do not think I will ever park to make out as long as I live. I hope this does the same for other kids.*

Once a critical mass of people knows an urban legend, the rate at which it spreads grows exponentially. The internet now enables urban legends (and everything else) to pass between people faster. Although a legend might also be disproved faster, that's a complicated mess. For now, as Lefty says in *Donnie Brasco*, "Forget about it."

The more people who believe a story, the more believable it seems. This effect is exacerbated when media outlets or local police fall for the legends and issue warnings.

Urban legends often then appear in popular culture (for example, "The Hook" inspired a *Supernatural* episode) and become part of our modern culture. The majority of people stop believing them, yet the stories linger in different forms.

Changes in Governments and Revolutions

From a distance, it can seem shocking when the people of a country revolt and overthrow dominant powers in a short time.

What is it that makes this sudden change happen? The answer is the formation of a critical mass of people necessary to move marginal ideas to a majority consensus. Pyotr

Kropotkin wrote:

Finally, our studies of the preparatory stages of all revolutions bring us to the conclusion that not a single revolution has originated in parliaments or in any other representative assembly. All began with the people. And no revolution has appeared in full armor — born, like Minerva out of the head of Jupiter, in a day. They all had their periods of incubation during which the masses were very slowly becoming imbued with the revolutionary spirit, grew bolder, commenced to hope, and step by step emerged from their former indifference and resignation. And the awakening of the revolutionary spirit always took place in such a manner that at first, single individuals, deeply moved by the existing state of things, protested against it, one by one. Many perished, "uselessly," the armchair critic would say. But the indifference of society was shaken by these progenitors. The dullest and most narrow-minded people were compelled to reflect, "Why should men, young, sincere, and full of strength, sacrifice their lives in this way?" It was impossible to remain indifferent; it was necessary to take a stand, for, or against: thought was awakening. Then, little by little, small groups came to be imbued with the same spirit of revolt; they also rebelled — sometimes in the hope of local success — in strikes or in small revolts against some official whom they disliked, or in order to get food for their hungry children, but frequently also without any hope of success: simply because the conditions grew unbearable. Not one, or two, or tens, but hundreds of similar revolts have preceded and must precede every revolution.

When an oppressive regime is in power, a change is inevitable. However, it is almost impossible to predict when that change will occur. Often, a large number of people want change and yet fear the consequences or lack the information necessary to join forces. When single individuals act upon their feelings, they are likely to be punished without having any real impact. Only when a critical mass of people's desire for change overwhelms their fear can a revolution occur. Other people are encouraged by the first group, and the idea spreads rapidly.

One example occurred in China in 1989. While the desire for change was almost universal, the consequences felt too dire. When a handful of students protested for reform in Beijing, authorities did not punish them. We have all seen the classic image of a lone student, shopping bags in hand, standing in front of a procession of tanks and halting them. Those few students who protested were the critical mass. Demonstrations erupted in more than 300 towns all over the country as people found the confidence to act.

Malcolm Gladwell on Tipping Points

An influential text on the topic of critical mass is Malcolm Gladwell's *The Tipping Point*. Published in 2000, the book describes a tipping point as "the moment of critical mass, the threshold, the boiling point." He notes that "Ideas and products and messages and behaviors spread just like viruses do" and cites such examples as the sudden popularity of Hush Puppies and the steep drop in crime in New York after 1990. Gladwell writes that although the world "may seem like an immovable, implacable place," it isn't. "With the slightest push — in just the right place — it can be tipped."

Referring to the 80/20 rule (also known as Pareto's principle), Gladwell explains how it takes a tiny number of people to kickstart the tipping point in any sort of epidemic:

Economists often talk about the 80/20 Principle, which is the idea that in any situation roughly 80 percent of the "work" will be done by 20 percent of the participants. In most societies, 20 percent of criminals commit 80 percent of crimes. Twenty percent of motorists cause 80 percent of all accidents. Twenty percent of beer drinkers drink 80 percent of all beer. When it comes to epidemics, though, this disproportionality becomes even more extreme: a tiny percentage of people do the majority of the work.

Rising crime rates are also the result of a critical mass of people who see unlawful behavior as justified, acceptable, or necessary. It takes only a small number of people who commit crimes for a place to seem dangerous and chaotic. Gladwell explains how minor transgressions lead to more serious problems:

[T]he Broken Windows theory ... was the brainchild of the criminologist James Q. Wilson and George Kelling. Wilson and Kelling argued that crime is the inevitable result of disorder. If a window is broken and left unrepaired, people walking by will conclude that no one cares and no one is in charge. Soon, more windows will be broken, and the sense of anarchy will spread from the building to the street it faces, sending a signal that anything goes. In a city, relatively minor problems like graffiti, public disorder, and aggressive panhandling, they write, are all the equivalent of broken windows, invitations to more serious crimes...

According to Gladwell's research, there are three main factors in the creation of a critical mass of people necessary to induce a sudden change.

The first of these is the Law of the Few. Gladwell states that certain categories of people are instrumental in the creation of tipping points. These categories are:

- **Connectors:** We all know connectors. These are highly gregarious, sociable people with large groups of friends. Connectors are those who introduce us to other people, instigate gatherings, and are the fulcrums of social groups. Gladwell defines connectors as those with networks of over one hundred people. An example of a cinematic connector is Kevin Bacon. There is a trivia game known as "Six Degrees of Kevin Bacon," in which players aim to connect any actor/actress to him within a

chain of six films. Gladwell writes that connectors have “some combination of curiosity, self-confidence, sociability, and energy.”

- **Mavens:** Again, we all know a maven. This is the person we call to ask what brand of speakers we should buy, or which Chinese restaurant in New York is the best, or how to cope after a rough breakup. Gladwell defines mavens as “people we rely upon to connect us with new information.” These people help create a critical mass due to their habit of sharing information, passing knowledge on through word of mouth.
- **Salesmen:** Whom would you call for advice about negotiating a raise, a house price, or an insurance payout? That person who just came to mind is probably what Gladwell calls a salesman. These are charismatic, slightly manipulative people who can persuade others to accept what they say.

The second factor cited by Gladwell is the “stickiness factor.” This is what makes a change significant and memorable. Heroin is sticky because it is physiologically addictive. Twitter is sticky because we want to keep returning to see what is being said about and to us. *Game of Thrones* is sticky because viewers are drawn in by the narrative and want to know what happens next. Once something reaches a critical mass, stickiness can be considered to be the rate of decline. The more sticky something is, the slower its decline. Cat videos aren’t very sticky, so even the viral ones thankfully fade into the night quickly. Finally, the third factor is the specific context; the circumstances, time, and place must be right for an epidemic to occur. Understanding how a tipping point works can help to clarify the concept of critical mass.

The 10% Rule

One big question is: what percentage of a population is necessary to create a critical mass?

According to researchers at Rensselaer Polytechnic Institute, the answer is a mere 10%. Computational analysis was used to establish where the shift from minority to majority lies. According to director of research Boleslaw Szymanski:

When the number of committed opinion holders is below 10 percent, there is no visible progress in the spread of ideas. It would literally take the amount of time comparable to the age of the universe for this size group to reach the majority. Once that number grows above 10 percent, the idea spreads like flame.

The research has shown that the 10% can comprise literally anyone in a given society. What matters is that those people are set in their beliefs and do not respond to pressure to change them. Instead, they pass their ideas on to others. (I’d argue that the percentage is lower. Much lower. See [Dictatorship of the Minority](#).)

As an example, Szymanski cites the sudden revolutions in countries such as Egypt and Tunisia: “In those countries, dictators who were in power for decades were suddenly overthrown in just a few weeks.”

According to another researcher:

In general, people do not like to have an unpopular opinion and are always seeking to try locally to come to a consensus ... As agents of change start to convince more and more people, the situation begins to change. People begin to question their own views at first and then completely adopt the new view to spread it even further. If the true believers just influenced their neighbors, that wouldn’t change anything within the larger system, as we saw with percentages less than 10.

The potential use of this knowledge is tremendous. Now that we know how many people are necessary to form a critical mass, this information can be manipulated — for good or evil. The choice is yours.

112. Attrition Warfare: When Even Winners Lose

When warring opponents use similar approaches and possess similar weapons, trench warfare becomes inevitable. The winning side usually has a slight advantage in production capability or resources.

It's hard to see when you're in it, but most people and businesses are in some form of attrition warfare. The best way out is to use a different approach — through tactics, strategy, or weaponry.

"When you do as everyone else does, don't be surprised when you get what everyone else gets."

— Peter Kaufman

The *International Encyclopedia of the First World War* defines attrition warfare as "the sustained process of wearing down an opponent so as to force their physical collapse through continuous losses in personnel, equipment and supplies or [wearing] them down to such an extent that their will to fight collapses."

Attrition warfare is considered a somewhat dirty tactic, although necessary in some situations. Indeed, theorists are divided as to whether attrition is even a separate tactic, rather than a ubiquitous feature of all conflict.

Traditional military theorists such as Sun Tzu ("Supreme excellence consists of breaking the enemy's resistance without fighting") and Machiavelli ("Never attempt to win by force what can be won by deception") evangelized for clever tactics. These methods tend to result in far fewer casualties, waste fewer resources and are a display of superior intellect, rather than just strength.

Attrition warfare is usually a last resort only. And most of the time when you win, it's only temporary. By not scoring a decisive blow, the winners leave room for the losers to believe they can win the next time.

To understand attrition warfare, we can look at examples of how it works. Let's examine two wars where attrition played a substantial role.

Attrition Warfare in World War I

One of the clearest examples of attrition warfare is World War I, so much so that many historians refer to it as "the War of Attrition."

Military technology evolved at an unprecedented rate during the start of the 20th century, and the usual maneuvers and tactics were irrelevant. The large-scale recruitment of horses for cavalry officers, who were then pitted against shells and machine guns, provides a classic image of this sad discrepancy between what was understood and what was done. Raised on Tennyson's images of heroic hand-to-hand combat, soldiers found themselves instead confined to trenches in a vicious fight to gain territory, inch by inch. The goal for much of the war was for each side to amass artillery and troops faster than the other, in order to grind down defenses and sap resources. Both sides were reduced by pure attrition.

Trenches provided a somewhat effective means of protection, as long as soldiers remained within them. Perhaps the most poignant comment on this comes from Harry Patch, the longest surviving World War I soldier, who lived to 111: "If any man tells you he went over the top and he wasn't scared, he's a damn liar."

Even when territory was gained, moving the heavy weapons was difficult and predictable. Germany slowly lost strength, leading to the eventual failure of their army. In the process, millions of people died and vast sums of money were spent on ammunition and other resources.

Strategists and commanders were somewhat out of their depth, as no one had any real experience with this type of warfare. Leaving the trenches meant the loss of the most valuable resource — people — and the usual techniques were irrelevant.

This situation led to a stationary war, wherein each side engaged in an incessant hurling of ammunition in the hope of eroding the other's morale and supplies.

"The war will be ended by the exhaustion of nations rather than the victories of armies."

— Winston Churchill

In a paper entitled The Theories of Attrition versus Manoeuvre and the Levels of War, Abel J. Esterhuyse writes:

Although campaigns were conducted in different parts of the world, the First World War was largely restricted to a relatively small geographical area in Western Europe. It was characterised by high personnel and equipment losses; an inability to bring the war to a decisive end; and bloody attritional fighting where, in a number of cases, the aim was to conquer terrain with no tactical and strategic value. This created an aversion to or negative view of an attritional war. It also contributed to a view that attrition required that terrain be occupied at all cost in order to ensure success.

We can also see the impact of attrition in the extensive efforts to boost the morale of those at home, far from the fighting — what was referred to as "the home front."

War is rarely what we imagine. Attrition warfare was not what people had in mind when they sent off their sons, husbands, and friends, or mailed white feathers to the "cowards" who did not go. The stark difference between early propaganda posters and later photographs of the actual fighting illustrates this disconnect.

In a war of attrition, morale is one of the key resources. Initiatives such as the donation of kettles to make airplanes, the growing of cabbages in rose beds, and letters sent to those in the trenches did little to further the pursuit of peace but did much to keep people hopeful.

Historians and military theorists have asserted that the use of attrition was not altogether a strategic one. Much of World War I was characterized by indecision and poor communication, as commanders grappled with slow technology and the difficulty of seeing the bigger picture.

It's not uncommon in war to develop a chessboard-style mentality, wherein commanders are not averse to sacrificing human life for the sake of a strategic advantage.

One particular battle from World War I which stands out as a notable example of attrition warfare is the Battle of Verdun. Occurring in France over 303 days, it involved a standoff between the German and French forces.

The German army intended to capture hills in the area, thereby gaining an elevated point for strategic maneuvers. Early success boosted German morale before their progress slowed to a glacial crawl.

The French army was ordered not to withdraw under any circumstances and to sustain consistent counter-attacks. Regularly switching tactics, the German army continued trying to gain more useful territory.

By July, the battle of the Somme was in full force and the Germans subsequently had fewer resources — a bad position to be in during a war of attrition. Territory was gained and lost numerous times, with a single village switching hands 16 times between June and August.

As German resources were further reduced, commanders resorted to deceit (which is also not compatible with attrition). By the time the French army reclaimed the lost territory, the Battle of Verdun had morphed into one of the deadliest and most expensive battles ever. Estimates of the number of deaths range from 700,000 to nearly 1 million.

From the start, the Battle of Verdun was fought upon a foundation of attrition. Both sides were essentially trapped, with no option but to keep trying to force the other into submission. Both sides were using similar approaches with similar capabilities.

Much has been written about the tactics used, with some critics stating that the use of attrition was a necessity due to poor judgment, rather than being a considered choice. It also illustrates a problematic element of attrition warfare: Once a substantial number of lives have been lost, commanders are motivated to continue a battle for longer than is wise in an attempt to justify those losses — a deadly instance of the sunk costs fallacy. In *The Price of Glory*, Alistair Horne quotes the diary of a French lieutenant who fought at Verdun: “Humanity is mad. It must be mad to do what it is doing. What a massacre! What scenes of horror and carnage! I cannot find words to translate my impressions. Hell cannot be so terrible. Men are mad!” He was killed a short time later as a result of a shell explosion. Horne also quotes a German soldier: “[The war would not be over] until the last German and the last French hobbled out of the trenches to exterminate each other with pocket knives.”

Attrition Warfare in the Vietnam War

The Vietnam War is another key example of attrition warfare. North Vietnam (aided by China, the Soviet Union, and other communist nations) fought South Vietnam (aided by the US, South Korea, Thailand, Australia and others). Spread over Laos, Cambodia, and Vietnam, the war lasted almost 20 years.

Much like World War II, the Vietnam War left an indelible mark on the affected nations and people. It was characterized by extreme brutality and human suffering — a ubiquitous feature of attrition warfare.

In an attempt to either prevent or foster the growth of communism, dominant world powers faced each other in appalling conditions. Somewhere in the region of 1.4–3.4 million lives were lost in the fight to prevent an economic model from spreading. Ten percent of South Vietnam was destroyed with Agent Orange in a bid to cut off food supplies, leading to hundreds of thousands of birth defects.

In the early 1960s, the US began to send troops to Vietnam (then known as French Indochina). Borders and old alliances were forgotten as the fighting spread over the following two decades.

Guerrilla warfare clashed with attrition. Struggling to compete with an unpredictable guerrilla insurgency (which included raids, sabotage and ambushes), the US army turned to attrition and sought to kill as many Vietnamese people as possible. Rather than aiming to gain territory as in typical conflicts, the goal was to reach the highest feasible body count in order to batter Vietnam into submission.

In *Kill Anything That Moves*, Nick Turse paints a stark portrait of the use of attrition warfare in the Vietnam War:

In Vietnam, the statistically minded war managers focused, above all, on the notion of achieving a “crossover point”: the moment when American soldiers would be killing more enemies than their Vietnamese opponents could replace... Producing a high body count was crucial for promotion in the officer corps. Many high-level officers established “production quotas” for their units, and systems of “debit” and “credit” to calculate exactly how efficiently subordinate units and middle-management personnel performed. Different formulas were used, but the commitment to war as a rational production process was common to all.

In many cases, attrition warfare can become a process of attempting to outright annihilate an opponent.

In Vietnam, uncertainty as to who the enemy was turned every non-American into a target. *The Americans never really grasped who the enemy was... they assumed that most villagers either were in league with the enemy or were guerrillas themselves once the sun went down... Farmers simply wanted nothing to do with the conflict or abstract notions like nationalism and communism... But bombs and napalm don’t discriminate. As gunships and howitzers ravaged the landscape... Vietnamese villages of every type ... perished in vast numbers.”*

Guerrilla warfare is the inverse of attrition: unstructured, fragmented and based on tactics, not force. It can take a large force engaging in attrition to defeat a small one engaged in guerrilla warfare.

Vietnamese revolutionary forces decisively outgunned by their adversaries, relied heavily on mines and other booby traps, as well as sniper fire and ambushes... Unable to deal with an enemy that overwhelmingly dictated the time, place, and duration of combat, US forces took to destroying whatever they could manage.

The Issues With Attrition Warfare

Among the many problems with attrition warfare are these:

- High death tolls — This is the primary issue. Although all wars involve casualties, attrition warfare increases the number of combatants and civilians who are killed.
- High costs — Attrition warfare requires a lot of resources. Adjusting for inflation, the Vietnam war cost \$770 billion, plus \$1 trillion for subsequent veterans benefits. Those figures do not even take into account the impact on industries and economies.
- The potential for abuse — When maximum damage is the goal, there is more potential for war crimes to occur and for people to abuse their power.
- Long durations — A war of attrition may be lengthy and slow moving. As Sun Tzu wrote, “there is no instance of a country having benefited from prolonged warfare.”
- The potential for an unstable outcome — The outcome of attrition warfare is not always clear. A nation which is battered into submission may rebel in the future, and tensions are exacerbated. The unstable outcome of World War I is in part responsible for the outbreak of World War II.
- Long-term impact on a nation — Attrition warfare can cause serious long-term problems for both sides. The deaths of large numbers of young, mostly male combatants can lead to a dramatic drop in birth rates for years to come. It is estimated that World War I led to 3.2 million fewer births than would have been expected in Germany alone. Fewer people to work during and after a war means a decrease in productivity and a change in the structure of economies. Money spent on fighting a war of attrition cannot be used for other areas, such as healthcare. Educational institutions often suffer, as young people are less able to attend. Large areas of land are destroyed, damaging farmland, homes, and infrastructure. It can take decades for a nation to recover from the impact of attrition warfare.

Attrition in Business — and Two Ways Out

The concept of attrition applies outside of war. Bureaucracies grind people out. Excessive competition among businesses might be good for consumers, but it's a grind for the companies involved.

There are two ways out that seem important.

The first option is that after you recognize that you're mired in attrition, you can, of course, opt out. Maybe if you put aside your ego, you'll decide that the time and resources required to compete are too much.

The second option might appeal more. History shows that the way out of trench warfare is the use of asymmetric weaponry. If you're using basically the same strategy with basically the same resources as your competitor, you're in a war of attrition. If, however, you choose a radically different strategy, with the same resources or fewer, you're likely not to be in a war of attrition. Of course, if you're right and your radically different strategy succeeds, you get the spoils. If you're wrong and your strategy fails, you get the humiliation of being

wrong. And since the world rewards conventional failure and not unconventional failure, you've got a difficult choice to make.

113. How Filter Bubbles Distort Reality: Everything You Need to Know

We find ourselves in a filter bubble any time we're only surrounded by views and opinions we agree with, while being sheltered from opposing perspectives. Filter bubbles distort our understanding of the world and hamper our ability to make balanced decisions. Here's how to pop the bubble.

The Basics

Read the headline, tap, scroll, tap, tap, scroll.

It is a typical day and you are browsing your usual news site. The New Yorker, BuzzFeed, The New York Times, BBC, The Globe and Mail, take your pick. As you skim through articles, you share the best ones with like-minded friends and followers. Perhaps you add a comment.

Few of us sit down and decide to inform ourselves on a particular topic. For the most part, we pick up our smartphones or open a new tab, scroll through a favored site and click on whatever looks interesting. Or we look at Facebook or Twitter feeds to see what people are sharing. Chances are high that we are not doing this intending to become educated on a certain topic. No, we are probably waiting in line, reading on the bus or at the gym, procrastinating, or grappling with insomnia, looking for some form of entertainment.

We all do this skimming and sharing and clicking, and it seems so innocent. But many of us are uninformed about or uninterested in the forces affecting what we see online and how content affects us in return — and that ignorance has consequences.

The term “filter bubble” refers to the results of the algorithms that dictate what we encounter online. According to Eli Pariser, those algorithms create “a unique universe of information for each of us ... which fundamentally alters the way we encounter ideas and information.”

Many sites offer personalized content selections, based on our browsing history, age, gender, location, and other data. The result is a flood of articles and posts that support our current opinions and perspectives to ensure that we enjoy what we see. Even when a site is not offering specifically targeted content, we all tend to follow people whose views align with ours. When those people share a piece of content, we can be sure it will be something we are also interested in.

That might not sound so bad, but filter bubbles create echo chambers. We assume that everyone thinks like us, and we forget that other perspectives exist.

Filter bubbles transcend web surfing. In important ways, your social circle is a filter bubble; so is your neighborhood. If you're living in a gated community, for example, you might think that reality is only BMWs, Teslas, and Mercedes. Your work circle acts as a filter bubble, too, depending on whom you know and at what level you operate.

One of the great problems with filters is our human tendency to think that what we see is all there is, without realizing that what we see is being filtered.

Eli Pariser on Filter Bubbles

The concept of filter bubbles was first identified by Eli Pariser, executive of Upworthy, activist, and author. In his revolutionary book *Filter Bubbles*, Pariser explained how Google searches bring up vastly differing results depending on the history of the user. He cites an example in which two people searched for “BP” (British Petroleum). One user saw news related to investing in the company. The other user received information about a recent oil spill.

Pariser describes how the internet tends to give us what we want:

Your computer monitor is a kind of one-way mirror, reflecting your own interests while algorithmic observers watch what you click.

Pariser terms this reflection a filter bubble, a “personal ecosystem of information.” It insulates us from any sort of cognitive dissonance by limiting what we see. At the same time, virtually everything we do online is being monitored — for someone else’s benefit. Each time we click, watch, share, or comment, search engines and social platforms harvest information. In particular, this information serves to generate targeted advertisements. Most of us have experienced the odd sensation of *deja vu* as a product we took a look at online suddenly appears everywhere we go online, as well as in our email inboxes. Often this advertising continues until we succumb and purchase the product.

Targeted advertisements can help us to find what we need with ease, but costs exist: *Personalization is based on a bargain. In exchange for the service of filtering, you hand large companies an enormous amount of data about your daily life — much of which you might not trust your friends with.*

The internet has changed a great deal from the early days, when people worried about strangers finding out who they were. Anonymity was once king. Now, our privacy has been sacrificed for the sake of advertising revenue:

What was once an anonymous medium where anyone could be anyone—where, in the words of the famous New Yorker cartoon, nobody knows you’re a dog—is now a tool for soliciting and analyzing our personal data. According to one Wall Street Journal study, the top fifty Internet sites, from CNN to Yahoo to MSN, install an average of 64 data-laden cookies and personal tracking beacons each. Search for a word like “depression” on Dictionary.com, and the site installs up to 223 tracking cookies and beacons on your computer so that other Web sites can target you with antidepressants. Share an article about cooking on ABC News, and you may be chased around the Web by ads for Teflon-coated pots. Open—even for an instant—a page listing signs that your spouse may be cheating and prepare to be haunted with DNA paternity-test ads. The new Internet doesn’t just know you’re a dog; it knows your breed and wants to sell you a bowl of premium kibble.

The sources of this information can be unexpected. Companies gather it from places we might not even consider:

When you read books on your Kindle, the data about which phrases you highlight, which pages you turn, and whether you read straight through or skip around are all fed back into Amazon’s servers and can be used to indicate what books you might like next. When you log in after a day reading Kindle e-books at the beach, Amazon can subtly customize its site to appeal to what you’ve read: If you’ve spent a lot of time with the latest James Patterson, but only glanced at that new diet guide, you might see more commercial thrillers and fewer health books.

One fact is certain. The personalization process is not crude or random. It operates along defined guidelines which are being refined every day. Honing occurs both on the whole and for individuals:

Most personalized filters are based on a three-step model. First, you figure out who people are and what they like. Then, you provide them with content and services that best fit them. Finally, you tune to get the fit just right. Your identity shapes your media. There’s just one flaw in this logic: Media also shape identity. And as a result, these services may end up creating a good fit between you and your media by changing ... you.

In *The Shallows*, Nicholas Carr also covers online information collection. Carr notes that the more time we spend online, the richer the information we provide:

The faster we surf across the surface of the Web—the more links we click and pages we view—the more opportunities Google gains to collect information about us and to feed us advertisements. Its advertising system, moreover, is explicitly designed to figure out which messages are most likely to grab our attention and then to place those messages in our field of view. Every click we make on the Web marks a break in our concentration, a

bottom-up disruption of our attention—and it's in Google's economic interest to make sure we click as often as possible.

Every single person who has ever spent time on the web knows how addictive the flow of stimulating information can be. No matter how disciplined we otherwise are, we cannot resist clicking related articles or scrolling through newsfeeds. There is a reason for this, as Pariser writes:

Personalized filters play to the most compulsive parts of you, creating “compulsive media” to get you to click things more.

In an attention economy, filter bubbles assist search engines, websites, and platforms in their goal to command the maximum possible share of our online time.

The Impact of Filter Bubbles

Each new technology brings with it a whole host of costs and benefits. Many are realized only as time passes. The invention of books led people to worry that memory and oral tradition would erode. Paper caused panic as young people switched from slates to this newfangled medium. Typewriters led to discussions of morality as female typists entered the job force and “distracted” men. The internet has been no exception. If anything, the issues presented by it are unique only in their complex intensity.

In particular, the existence of filter bubbles has led to widespread concern. Pariser writes:

Democracy requires citizens to see things from one another's point of view, but instead we're more and more enclosed in our own bubbles. Democracy requires a reliance on shared facts; instead we're being offered parallel but separate universes.

... Personalization filters serve a kind of invisible autopropaganda, indoctrinating us with our own ideas, amplifying our desire for things that are familiar and leaving us oblivious to the dangers lurking in the dark territory of the unknown.

Pariser quotes Jon Chait as saying:

Partisans are more likely to consume news sources that confirm their ideological beliefs.

People with more education are more likely to follow political news. Therefore, people with more education can actually become mis-educated.

Many people have debated the impact of filter bubbles on the recent US election and the Brexit vote. In both cases, large numbers of people were shocked by the outcome. Even those within the political and journalistic worlds expected the inverse results.

“We become, neurologically, what we think.”

— Nicholas Carr

In the case of the Brexit vote, a large percentage of those who voted to leave the European Union were older people who are less active online, meaning that their views are less visible. Those who voted to remain tended to be younger and more active online, meaning that they were in an echo chamber of similar attitudes.

Democracy requires everyone to be equally informed. Yet filter bubbles are distorting our ideas of the world. In a paper for Princeton University, Jacob N. Shapiro revealed the extent of the influence on our voting:

The results of these experiments demonstrate that (i) biased search rankings can shift the voting preferences of undecided voters by 20% or more, (ii) the shift can be much higher in some demographic groups, and (iii) search ranking bias can be masked so that people show no awareness of the manipulation. We call this type of influence, which might be applicable to a variety of attitudes and beliefs, the search engine manipulation effect.

Given that many elections are won by small margins, our results suggest that a search engine company has the power to influence the results of a substantial number of elections with impunity. The impact of such manipulations would be especially large in countries dominated by a single search engine company.

Filter bubbles do not just occur on the internet. Shapiro provides an example from a decade ago of TV shifting the results of elections:

It is already well established that biased media sources such as newspapers, political polls, and television sway voters. A 2007 study by DellaVigna and Kaplan found, for example, that whenever the conservative-leaning Fox television network moved into a new market in the United States, conservative votes increased, a phenomenon they labeled the Fox News Effect. These researchers estimated that biased coverage by Fox News was sufficient to shift 10,757 votes in Florida during the 2000 US Presidential election: more than enough to flip the deciding state in the election, which was carried by the Republican presidential candidate by only 537 votes. The Fox News Effect was also found to be smaller in television markets that were more competitive.

However, Shapiro believes the internet has a more dramatic effect than other forms of media:

Search rankings are controlled in most countries today by a single company. If, with or without intervention by company employees, the algorithm that ranked election-related information favored one candidate over another, competing candidates would have no way of compensating for the bias. It would be as if Fox News were the only television network in the country. Biased search rankings would, in effect, be an entirely new type of social influence, and it would be occurring on an unprecedented scale. Massive experiments conducted recently by social media giant Facebook have already introduced other unprecedented types of influence made possible by the Internet. Notably, an experiment reported recently suggested that flashing "VOTE" advertisements to 61 million Facebook users caused more than 340,000 people to vote that day who otherwise would not have done so.

In the US election and the Brexit vote, filter bubbles caused people to become insulated from alternative views. Some critics have theorized that the widespread derision of Trump and Leave voters led them to be less vocal, keeping their opinions within smaller communities to avoid confrontation. Those who voted for Clinton or to Remain loudly expressed themselves within filtered communities. Everyone, it seemed, agreed with each other. Except, they didn't, and no one noticed until it was too late.

A further issue with filter bubbles is that they are something we can only opt out of, not something we consent to. As of March 2017, an estimated 1.94 billion people have a Facebook account, of which 1.28 billion log on every day. It is safe to assume that only a small percentage are informed about the algorithms. Considering that 40% of people regard Facebook as their main news source, this is worrying. As with cognitive biases, a lack of awareness amplifies the impact of filter bubbles.

We have minimal concrete evidence of exactly what information search engines and social platforms collect. Even SEO (search engine optimization) experts do not know for certain how search rankings are organized. We also don't know if sites collect information from users who do not have accounts.

Scandals are becoming increasingly common, as sites and services are found to be harvesting details without consent. For example, Evernote came under fire when documents revealed that staff members can access documents, and Unroll's nasty habit of selling details of user email habits led to criticism. Even when this information is listed in user agreements or disclaimers, it can be difficult for users to ascertain from the confusing jargon how their data are being used, by whom, and why.

In his farewell speech, President Obama aired his personal concerns:

[We] retreat into our own bubbles, ... especially our social media feeds, surrounded by people who look like us and share the same political outlook and never challenge our assumptions. ... And increasingly, we become so secure in our bubbles that we start accepting only information, whether it's true or not, that fits our opinions, instead of basing our opinions on the evidence that is out there.

Filter bubbles can cause cognitive biases and shortcuts to manifest, amplifying their negative impact on our ability to think in a logical and critical manner. A combination of social proof, availability bias, confirmation bias, and bias from disliking/liking is prevalent. As Pariser writes:

The filter bubble tends to dramatically amplify confirmation bias—in a way, it's designed to. Consuming information that conforms to our ideas of the world is easy and pleasurable; consuming information that challenges us to think in new ways or question our assumptions is frustrating and difficult. This is why partisans of one political stripe tend not to consume the media of another. As a result, an information environment built on click signals will favor content that supports our existing notions about the world over content that challenges them.

Pariser sums up the result of extensive filtration: “A world constructed from the familiar is the world in which there’s nothing to learn.”

Filter Bubbles and Group Psychology

We have an inherent desire to be around those who are like us and reinforce our worldview. Our online behavior is no different. People form tribes based on interests, location, employment, affiliation, and other details. These groups — subreddits, Tumblr fandoms, Facebook groups, Google+ circles, etc. — have their own rules, conventions, in-jokes, and even vocabulary. Within groups (even if members never meet each other), beliefs intensify. Anyone who disagrees may be ousted from the community. Sociologists call this behaviour “communal reinforcement” and stress that the ideas perpetuated can have no relation to reality or empirical evidence.

“When you’re asked to fight a war that’s over nothing, it’s best to join the side that’s going to win.”

— Conor Oberst

Communal reinforcement can be positive. Groups geared towards people with mental health problems, chronic illnesses, addictions, and other issues are often supportive and assist many people who might not have another outlet.

However, when a group is encased within a filter bubble, it can lead to groupthink. This is a psychological phenomenon wherein groups of people experience a temporary loss of the ability to think in a rational, moral and realistic manner. When the members of a group are all exposed to the same confirmatory information, the results can be extreme. Symptoms include being excessively optimistic, taking risks, ignoring legal and social conventions, regarding those outside the group as enemies, censoring opposing ideas, and pressuring members to conform. As occurred with the US election and the Brexit vote, those experiencing groupthink within a filter bubble see themselves as in the right and struggle to consider alternative perspectives.

For example, imagine a Facebook group for Trump supporters in the months prior to the election. Members share pro-Trump news items, discuss policies and circulate cohesive information among themselves. Groupthink sets in, as the members selectively process information, fail to evaluate alternative viewpoints, fail to consider risks, haze any members who disagree, and even ignore the possibility of a negative outcome. From the outside, we can see the issues with a combination of filter bubbles and groupthink, but they can be hard to identify from the inside.

How Can We Avoid Filter Bubbles?

Thankfully, it is not difficult to pop the filter bubble if we make an effort to do so. Methods for doing this include:

- Using ad-blocking browser extensions. These remove the majority of advertisements from websites we visit. The downside is that most sites rely on

advertising revenue to support their work, and some (such as Forbes and Business Insider) insist on users' disabling ad blockers before viewing a page.

- Reading news sites and blogs which aim to provide a wide range of perspectives. Pariser's own site, Upworthy, aims to do this. Others, including The Wall Street Journal, the New Yorker, BBC, and AP news claim to offer a balanced view of the world. Regardless of the sources we frequent, a brief analysis of the front page will provide a good idea of any biases. In the wake of the US election, a number of newsletters, sites, apps, and podcasts are working to pop the filter bubble. An excellent example is Colin Wright's podcast, Let's Know Things (<http://letsknowthings.com/>), which examines a news story in context each week.
- Switching our focus from entertainment to education. As Nicholas Carr writes in *The Shallows*: "The Net's interactivity gives us powerful new tools for finding information, expressing ourselves, and conversing with others. It also turns us into lab rats constantly pressing levers to get tiny pellets of social or intellectual nourishment."
- Using Incognito browsing, deleting our search histories, and doing what we need to do online without logging into our accounts.
- Deleting or blocking browser cookies. For the uninitiated, many websites plant "cookies" (small text files) each time we visit them; those cookies are then used to determine what content to show us. Cookies can be manually deleted, and browser extensions are available which remove them. In some instances, cookies are useful, so removal should be done with discretion.

Fish don't know they are in the water and we don't know we are in a filter bubble unless we take the effort to (as David Bowie put it) leave the capsule — if you dare.

In shaping what we see, filter bubbles show us a distorted map and not the terrain. In so doing, they trick our brains into thinking that this is the reality. As technology improves and the ability of someone like the NYT, say, to show the same story to 100 different people using 100 different ways, the filter bubble becomes deeper. We lose track of what's filtered and what's not as the news becomes tailored to cement our existing opinions. After all, everyone wants to read a newspaper that agrees with them.

Systems — be they people, cultures, or web browsing, to name a few examples — naturally have to filter information and thus they reduce options. Sometimes people make decisions, sometimes cultures make them, and increasingly algorithms make them. As the speed of information flowing through these systems increases, filters will play an even more important role.

Understanding that what we see is not all there is will help us realize that we're living in a distorted world and remind us to take off the glasses.

114. The Butterfly Effect: Everything You Need to Know About This Powerful Mental Model

The butterfly effect is an often misunderstood phenomenon wherein a small change in starting conditions can lead to vastly different outcomes. Understanding the butterfly effect can give us a new lens through which to view business, markets, and more.

“You could not remove a single grain of sand from its place without thereby ... changing something throughout all parts of the immeasurable whole.”

— Fichte, *The Vocation of Man* (1800)

In one of Stephen King's greatest works, *11/22/63*, a young man named Jake discovers a portal in a diner's pantry which leads back to 1958. After a few visits and some experiments, Jake deduces that altering history is possible. However long he stays in the past, only two minutes go by in the present. He decides to live in the past until 1963 so he can prevent the assassination of President John F. Kennedy, believing that this change will greatly benefit humanity. After years of stalking Lee Harvey Oswald, Jake manages to prevent him from shooting Kennedy.

Upon returning to the present, he expects to find the world improved as a result. Instead, the opposite has happened. Earthquakes occur everywhere, his old home is in ruins, and nuclear war has destroyed much of the world. (As King wrote in an article for *Marvel Spotlight*, “Not good to fool with Father Time.”) Distraught, Jake returns to 1958 once again and resets history.

In addition to being a masterful work of speculative fiction, *11/22/63* is a classic example of how everything in the world is connected together.

The butterfly effect is the idea that small things can have non-linear impacts on a complex system. The concept is imagined with a butterfly flapping its wings and causing a typhoon. Of course, a single act like the butterfly flapping its wings cannot cause a typhoon. Small events can, however, serve as catalysts that act on starting conditions.

And as John Gribbin writes in his cult-classic work *Deep Simplicity*, “some systems ... are very sensitive to their starting conditions, so that a tiny difference in the initial ‘push’ you give them causes a big difference in where they end up, and there is feedback, so that what a system does affects its own behavior.”

In the foreword to *The Butterfly Effect in Competitive Markets* by Dr. Rajagopal, Tom Breuer writes:

Simple systems, with few variables, can nonetheless show unpredictable and sometimes chaotic behavior...[Albert] Libchaber conducted a series of seminal experiments. He created a small system in his lab to study convection (chaotic system behavior) in a cubic millimeter of helium. By gradually warming this up from the bottom, he could create a state of controlled turbulence. Even this tightly controlled environment displayed chaotic behavior: complex unpredictable disorder that is paradoxically governed by “orderly” rules. ... [A] seemingly stable system (as in Libchaber’s 1 ccm cell of helium) can be exposed to very small influences (like heating it up a mere 0.001 degree), and can transform from orderly convection into wild chaos. Although [such systems are] governed by deterministic phenomena, we are nonetheless unable to predict how [they] will behave over time.

What the Butterfly Effect Is Not

The point of the butterfly effect is not to get leverage. As General Stanley McChrystal writes in *Team of Teams*:

In popular culture, the term “butterfly effect” is almost always misused. It has become synonymous with “leverage”—the idea of a small thing that has a big impact, with the implication that, like a lever, it can be manipulated to a desired end. This misses the point

of Lorenz's insight. The reality is that small things in a complex system may have no effect or a massive one, and it is virtually impossible to know which will turn out to be the case. Benjamin Franklin offered a poetic perspective in his variation of a proverb that's been around since the 14th century in English and the 13th century in German, long before the identification of the butterfly effect:

*For want of a nail the shoe was lost,
For want of a shoe the horse was lost,
For want of a horse the rider was lost,
For want of a rider the battle was lost,
For want of a battle the kingdom was lost,
And all for the want of a horseshoe nail.*

The lack of one horseshoe nail could be inconsequential, or it could indirectly cause the loss of a war. There is no way to predict which outcome will occur. (If you want an excellent kids book to start teaching this to your children, check out *If You Give a Mouse a Cookie*.)

In this post, we will seek to unravel the butterfly effect from its many incorrect connotations, and build an understanding of how it affects our individual lives and the world in general.

Edward Lorenz and the Discovery of the Butterfly Effect

"It used to be thought that the events that changed the world were things like big bombs, maniac politicians, huge earthquakes, or vast population movements, but it has now been realized that this is a very old-fashioned view held by people totally out of touch with modern thought. The things that change the world, according to Chaos theory, are the tiny things. A butterfly flaps its wings in the Amazonian jungle, and subsequently a storm ravages half of Europe."

— from Good Omens, by Terry Pratchett and Neil Gaiman

Although the concept of the butterfly effect has long been debated, the identification of it as a distinct effect is credited to Edward Lorenz (1917–2008). Lorenz was a meteorologist and mathematician who successfully combined the two disciplines to create chaos theory. During the 1950s, Lorenz searched for a means of predicting the weather, as he found linear models to be ineffective.

In an experiment to model a weather prediction, he entered the initial condition as 0.506, instead of 0.506127. The result was surprising: a somewhat different prediction. From this, he deduced that the weather must turn on a dime. A tiny change in the initial conditions had enormous long-term implications. By 1963, he had formulated his ideas enough to publish an award-winning paper entitled *Deterministic Nonperiodic Flow*. In it, Lorenz writes:

Subject to the conditions of uniqueness, continuity, and boundedness ... a central trajectory, which in a certain sense is free of transient properties, is unstable if it is nonperiodic. A noncentral trajectory ... is not uniformly stable if it is nonperiodic, and if it is stable at all, its very stability is one of its transient properties, which tends to die out as time progresses. In view of the impossibility of measuring initial conditions precisely, and thereby distinguishing between a central trajectory and a nearby noncentral trajectory, all nonperiodic trajectories are effectively unstable from the point of view of practical prediction.

In simpler language, he theorized that weather prediction models are inaccurate because knowing the precise starting conditions is impossible, and a tiny change can throw off the results. To make the concept understandable to non-scientific audiences, Lorenz began to use the butterfly analogy.

A small error in the initial data magnifies over time.

In speeches and interviews, he explained that a butterfly has the potential to create tiny changes which, while not creating a typhoon, could alter its trajectory. A flapping wing represents the minuscule changes in atmospheric pressure, and these changes compound as a model progresses. Given that small, nearly imperceptible changes can have massive implications in complex systems, Lorenz concluded that attempts to predict the weather were impossible. Elsewhere in the paper, he writes:

If, then, there is any error whatever in observing the present state—and in any real system such errors seem inevitable—an acceptable prediction of an instantaneous state in the distant future may well be impossible.

... In view of the inevitable inaccuracy and incompleteness of weather observations, precise very-long-range forecasting would seem to be nonexistent.

Lorenz always stressed that there is no way of knowing what exactly tipped a system. The butterfly is a symbolic representation of an unknowable quantity.

Furthermore, he aimed to contest the use of predictive models that assume a linear, deterministic progression and ignore the potential for derailment. Even the smallest error in an initial setup renders the model useless as inaccuracies compound over time. The exponential growth of errors in a predictive model is known as *deterministic chaos*. It occurs in most systems, regardless of their simplicity or complexity.

The butterfly effect is somewhat humbling—a model that exposes the flaws in other models. It shows science to be less accurate than we assume, as we have no means of making accurate predictions due to the exponential growth of errors.

Before the work of Lorenz, people assumed that an approximate idea of initial conditions would lead to an approximate prediction of the outcome. In *Chaos: Making a New Science*, James Gleick writes:

The models would churn through complicated, somewhat arbitrary webs of equations, meant to turn measurements of initial conditions ... into a simulation of future trends. The programmers hoped the results were not too grossly distorted by the many unavoidable simplifying assumptions. If a model did anything too bizarre ... the programmers would revise the equations to bring the output back in line with expectation... Models proved dismally blind to what the future would bring, but many people who should have known better acted as though they believed the results.

One theoretician declared, “The basic idea of Western science is that you don’t have to take into account the falling of a leaf on some planet in another galaxy when you’re trying to account for the motion of a billiard ball on a pool table on earth.”

An illustration of two weather conditions with very slightly different initial conditions. The trajectories are similar at first, before deviating further and further.

Lorenz’s findings were revolutionary because they proved this assumption to be entirely false. He found that without a perfect idea of initial conditions, predictions are useless—a shocking revelation at the time.

During the early days of computers, many people believed they would enable us to understand complex systems and make accurate predictions. People had been slaves to weather for millennia, and now they wanted to take control. With one innocent mistake, Lorenz shook the forecasting world, sending ripples which (appropriately) spread far beyond meteorology.

Ray Bradbury, the Butterfly Effect, and the Arrow of Time

Ray Bradbury’s classic science fiction story *A Sound of Thunder* predates the identification of chaos theory and the butterfly effect. Set in 2055, it tells of a man named Eckels who travels back 65 million years to shoot a dinosaur. Warned not to deviate from the tour guide’s plan, Eckels (along with his guide and the guide’s assistant) heads off to kill a Tyrannosaurus Rex who was going to die soon anyway when a falling tree lands on it.

Eckels panics at the sight of the creature and steps off the path, leaving his guide to kill the T Rex. The guide is enraged and orders Eckels to remove the bullets before the trio returns to 2055. Upon arrival, they are confused to find that the world has changed. Language is altered, and an evil dictator is now in charge. A confused Eckels notices a crushed butterfly stuck to his boot and realizes that in stepping off the path, he killed the insect and changed the future. Bradbury writes:

Eckels felt himself fall into a chair. He fumbled crazily at the thick slime on his boots. He held up a clod of dirt, trembling, "No, it cannot be. Not a little thing like that. No!"

Embedded in the mud, glistening green and gold and black, was a butterfly, very beautiful and very dead.

"Not a little thing like that! Not a butterfly!" cried Eckels.

It fell to the floor, an exquisite thing, a small thing that could upset balances and knock down a line of small dominoes and then big dominoes and then gigantic dominoes, all down the years across Time. Eckels' mind whirled. It couldn't change things. Killing one butterfly couldn't be that important! Could it?

Bradbury envisioned the passage of time as fragile and liable to be disturbed by minor changes. In the decades since the publication of *A Sound of Thunder*, physicists have examined its accuracy. Obviously, we cannot time-travel, so there is no way of knowing how plausible the story is, beyond predictive models. Bradbury's work raises the questions of what time is and whether it is deterministic.

Physicists refer to the Arrow of Time—the non-reversible progression of entropy (disorder.) As time moves forward, matter becomes more and more chaotic and does not spontaneously return to its original state. If you break an egg, it remains broken and cannot spontaneously re-form, for example. The Arrow of Time gives us a sense of past, present, and future. Arthur Eddington (the astronomer and physicist who coined the term) explained:

Let us draw an arrow arbitrarily. If as we follow the arrow we find more and more of the random element in the state of the world, then the arrow is pointing towards the future; if the random element decreases the arrow points towards the past. That is the only distinction known to physics. This follows at once if our fundamental contention is admitted that the introduction of randomness is the only thing which cannot be undone.

In short, the passage of time as we perceive it does exist, conditional to the existence of entropy. As long as entropy is non-reversible, time can be said to exist. The closest thing we have to a true measurement of time is a measurement of entropy. If the progression of time is nothing but a journey towards chaos, it makes sense for small changes to affect the future by amplifying chaos.

We do not yet know if entropy creates time or is a byproduct of it. Subsequently, we cannot know if changing the past would change the future. Would stepping on a butterfly shift the path of entropy? Did Eckels move off the path out of his own free will, or was that event predetermined? Was the dictatorial future he returned to always meant to be?

These interconnected concepts — the butterfly effect, chaos theory, determinism, free will, time travel — have captured many imaginations since their discoveries. Films ranging from *It's a Wonderful Life* to *Donnie Darko* and the eponymous *Butterfly Effect* have explored the complexities of cause and effect. Once again, it is important to note that works of fiction tend to view the symbolic butterfly as the cause of an effect. According to Lorenz's original writing, though, the point is that small details can tip the balance *without being identifiable*.

The Butterfly Effect in Business

Marketplaces are, in essence, chaotic systems that are influenced by tiny changes. This makes it difficult to predict the future, as the successes and failures of businesses can appear random. Periods of economic growth and decline sprout from nowhere. This is the

result of the exponential impact of subtle stimuli—the economic equivalent of the butterfly effect. Breuer explains:

We live in an interconnected, or rather a hyper-connected society. Organizations and markets “behave” like networks. This triggers chaotic (complex) rather than linear behavior.

Preparing for the future and seeing the logic in the chaos of consumer behavior is not easy. Once-powerful giants collapse as they fall behind the times. Tiny start-ups rise from the ashes and take over industries. Small alterations in existing technology transform how people live their lives. Fads capture everyone’s imagination, then disappear.

Businesses have two options in this situation: build a timeless product or service, or race to keep up with change. Many businesses opt for a combination of the two. For example, Doc Martens continues selling the classic 1460 boot, while bringing out new designs each season. This approach requires extreme vigilance and attention to consumer desires in an attempt to both remain relevant and appear timeless. Businesses leverage the compounding impact of small tweaks that aim to generate interest in all they have to offer.

In *The Butterfly Effect in Competitive Markets*, Dr. Rajagopal writes that most global firms are penetrating bottom-of-the-pyramid market segments by introducing small changes in technology, value perceptions, [and] marketing-mix strategies, and driving production on an unimagined scale of magnitude to derive a major effect on markets. ...Procter & Gamble, Kellogg’s, Unilever, Nestlé, Apple, and Samsung, have experienced this effect in their business growth... Well-managed companies drive small changes in their business strategies by nipping the pulse of consumers...

Most firms use such effect by making a small change in their strategy in reference to produce, price, place, promotion, ... posture (developing corporate image), and proliferation...to gain higher market share and profit in a short span.

For most businesses, incessant small changes are the most effective way to produce the metaphorical typhoon. These iterations keep consumers engaged while preserving brand identity. If these small tweaks fail, the impact is hopefully not too great. But if they succeed and compound, the rewards can be monumental.

By nature, all markets are chaotic, and what seem like inconsequential alterations can propel a business up or down. Rajagopal explains how the butterfly effect connects to business:

Globalization and frequent shifts in consumer preferences toward products and services have accelerated chaos in the market due to the rush of firms, products, and business strategies. Chaos theory in markets addresses the behavior of strategic and dynamic moves of competing firms that are highly sensitive to existing market conditions triggering the butterfly effect.

The initial conditions (economic, social, cultural, political) in which a business sets up are vital influences on its success or failure. Lorenz found that the smallest change in the preliminary conditions created a different outcome in weather predictions, and we can consider the same to be true for businesses. The first few months and years are a crucial time when rates of failure are highest and the basic brand identity forms. Any of the early decisions, achievements, or mistakes have the potential to be the wing flap that creates a storm.

Benoit Mandelbrot on the Butterfly Effect in Economics

International economies can be thought of as a single system, wherein each part influences the others. Much like the atmosphere, the economy is a complex system in which we see only the visible outcomes—rain or shine, boom, or bust. With the advent of globalization and improved communication technology, the economy is even more interconnected than in the past. One episode of market volatility can cause problems for the entire system. The butterfly effect in economics refers to the compounding impact of small changes. As a consequence, it is nearly impossible to make accurate predictions for

the future or to identify the precise cause of an inexplicable change. Long periods of stability are followed by sudden declines and vice versa.

Benoit Mandelbrot (the “father of fractals”) began applying the butterfly effect to economics several decades ago. In a 1999 article for *Scientific American*, he explained his findings. Mandelbrot saw how unstable markets could be, and he cited an example of a company which saw its stock drop 40% in one day, followed by another 6%, before rising by 10%—the typhoon created by an unseen butterfly. When Benoit looked at traditional economic models, he found that they did not even allow for the occurrence of such events. Standard models denied the existence of dramatic market shifts. Benoit writes in *Scientific American*:

According to portfolio theory, the probability of these large fluctuations would be a few millionths of a millionth of a millionth of a millionth. (The fluctuations are greater than 10 standard deviations.) But in fact, one observes spikes on a regular basis—as often as every month—and their probability amounts to a few hundredths.

If these changes are unpredictable, what causes them? Mandelbrot’s answer lay in his work on fractals. To explain fractals would require a whole separate post, so we will go with Mandelbrot’s own simplified description: “A fractal is a geometric shape that can be separated into parts, each of which is a reduced-scale version of the whole.” He goes on to explain the connection:

In finance, this concept is not a rootless abstraction but a theoretical reformulation of a down-to-earth bit of market folklore—namely that movements of a stock or currency all look alike when a market chart is enlarged or reduced so that it fits the same time and price scale. An observer then cannot tell which of the data concern prices that change from week to week, day to day or hour to hour. This quality defines the charts as fractal curves and makes available many powerful tools of mathematical and computer analysis.”

In a talk, Mandelbrot held up his coffee and declared that predicting its temperature in a minute is impossible, but in an hour is perfectly possible. He applied the same concept to markets that change in dramatic ways in the short term. Even if a long-term pattern can be deduced, it has little use for those who trade on a shorter timescale.

Mandelbrot explains how his fractals can be used to create a more useful model of the chaotic nature of the economy:

Instead, multifractals can be put to work to “stress-test” a portfolio. In this technique, the rules underlying multifractals attempt to create the same patterns of variability as do the unknown rules that govern actual markets. Multifractals describe accurately the relation between the shape of the generator and the patterns of up-and-down swings of prices to be found on charts of real market data... They provide estimates of the probability of what the market might do and allow one to prepare for inevitable sea changes. The new modeling techniques are designed to cast a light of order into the seemingly impenetrable thicket of the financial markets. They also recognize the mariner’s warning that, as recent events demonstrate, deserves to be heeded: On even the calmest sea, a gale may be just over the horizon.

In *The Misbehaviour of Markets*, Mandelbrot and Richard Hudson expand upon the topic of financial chaos. They begin with a discussion of the infamous 2008 crash and its implications:

The worldwide market crash of autumn 2008 had many causes: greedy bankers, lax regulators and gullible investors, to name a few. But there is also a less-obvious cause: our all-too-limited understanding of how markets work, how prices move and how risks evolve. ...

Markets are complex, and treacherous. The bone-chilling fall of September 29, 2008—a 7 percent, 777 point plunge in the Dow Jones Industrial Average—was, in historical terms, just a particularly dramatic demonstration of that fact. In just a few hours, more than \$1.6 trillion was wiped off the value of American industry—\$5 trillion worldwide.

Mandelbrot and Hudson believe that the 2008 credit crisis can be attributed in part to the increasing confidence in financial predictions. People who created computer models designed to guess the future failed to take into account the butterfly effect. No matter how complex the models became, they could not create a perfect picture of initial conditions or account for the compounding impact of small changes. Just as people believed they could predict and therefore control the weather before Lorenz published his work, people thought they could do the same for markets until the 2008 crash proved otherwise. Wall Street banks trusted their models of the future so much that they felt safe borrowing growing sums of money for what was, in essence, gambling. After all, their predictions said such a crash was impossible. Impossible or not, it happened.

According to Mandelbrot and Hudson, predictive models view markets as “a risky but ultimately ... manageable world.” As with meteorology, economic predictions are based on approximate ideas of initial conditions—ideas that, as we know, are close to useless. As Mandelbrot and Hudson write:

[C]auses are usually obscure. ... The precise market mechanism that links news to price, cause to effect, is mysterious and seems inconsistent. Threat of war: Dollar falls. Threat of war: Dollar rises. Which of the two will actually happen? After the fact, it seems obvious; in hindsight, fundamental analysis can be reconstituted and is always brilliant. But before the fact, both outcomes may seem equally likely.

In the same way that apparently similar weather conditions can create drastically different outcomes, apparently similar market conditions can create drastically different outcomes. We cannot see the extent to which the economy is interconnected, and we cannot identify where the butterfly lies. Mandelbrot and Hudson disagree with the view of the economy as separate from other parts of our world. Everything connects:

No one is alone in this world. No act is without consequences for others. It is a tenet of chaos theory that, in dynamical systems, the outcome of any process is sensitive to its starting point—or in the famous cliché, the flap of a butterfly's wings in the Amazon can cause a tornado in Texas. I do not assert that markets are chaotic.... But clearly, the global economy is an unfathomably complicated machine. To all the complexity of the physical world... you add the psychological complexity of men acting on their fleeting expectations....

Why do people prefer to blame crashes (such as the 2008 credit crisis) on the folly of those in the financial industry? Jonathan Cainer provides a succinct explanation:

Why do we love the idea that people might be secretly working together to control and organize the world? Because we do not like to face the fact that our world runs on a combination of chaos, incompetence, and confusion.

Historic Examples of the Butterfly Effect

*“A very small cause which escapes our notice determines a considerable effect that we cannot fail to see, and then we say the effect is due to chance. If we knew exactly the laws of nature and the situation of the universe at the initial moment, we could predict exactly the situation of that same universe at a succeeding moment. But even if it were the case that the natural laws had no longer any secret for us, we could still only know the initial situation *approximately*. If that enabled us to predict the succeeding situation with *the same approximation*, that is all we require, and we should say that the phenomenon had been predicted, that it is governed by laws. But it is not always so; it may happen that small differences in the initial conditions produce very great ones in the final phenomena. A small error in the former will produce an enormous error in the latter. Prediction becomes impossible, and we have the fortuitous phenomenon.”*

— Jules Henri Poincaré (1854–1912)

Many examples exist of instances where a tiny detail led to a dramatic change. In each case, the world we live in could be different if the situation had been reversed. Here are some examples of how the butterfly effect has shaped our lives.

- The bombing of Nagasaki. The US initially intended to bomb the Japanese city of Kuroko, with the munitions factory as a target. On the day the US planned to attack, cloudy weather conditions prevented the factory from being seen by military personnel as they flew overhead. The airplane passed over the city three times before the pilots gave up. Locals huddled in shelters heard the hum of the airplane preparing to drop the nuclear bomb and prepared for their destruction. Except Kuroko was never bombed. Military personnel decided on Nagasaki as the target due to improved visibility. The implications of that split-second decision were monumental. We cannot even begin to comprehend how different history might have been if that day had not been cloudy. Kuroko is sometimes referred to as the luckiest city in Japan, and those who lived there during the war are still shaken by the near-miss.
- The Academy of Fine Arts in Vienna rejecting Adolf Hitler's application, twice. In the early 1900s, a young Hitler applied for art school and was rejected, possibly by a Jewish professor. By his own estimation and that of scholars, this rejection went on to shape his metamorphosis from an aspiring bohemian artist into the human manifestation of evil. We can only speculate as to how history would have been different. But it is safe to assume that a great deal of tragedy could have been avoided if Hitler had applied himself to water colors, not to genocide.
- The assassination of Archduke Franz Ferdinand. A little-known fact about the event considered to be the catalyst for both world wars is that it almost didn't happen. On the 28th of June, 1914, a teenage Bosnian-Serb named Gavrilo Princip went to Sarajevo with two other nationalists to assassinate the Archduke. The initial assassination attempt failed; a bomb or grenade exploded beneath the car behind the Archduke's and wounded its occupants. The route was supposed to have been changed after that, but the Archduke's driver didn't get the message. Had he actually taken the alternate route, Princip would not have been on the same street as the car and would not have had the chance to shoot the Archduke and his wife that day. Were it not for a failure of communication, both world wars might never have happened.
- The Chernobyl disaster. In 1986, a test at the Chernobyl nuclear plant went awry and released 400 times the radiation produced by the bombing of Hiroshima. One hundred fifteen thousand people were evacuated from the area, with many deaths and birth defects resulting from the radiation. Even today, some areas remain too dangerous to visit. However, it could have been much worse. After the initial explosion, three plant workers volunteered to turn off the underwater valves to prevent a second explosion. It has long been believed that the trio died as a result, although there is now some evidence this may not have been the case. Regardless, diving into a dark basement flooded with radioactive water was a heroic act. Had they failed to turn off the valve, half of Europe would have been destroyed and rendered uninhabitable for half a million years. Russia, Ukraine, and Kiev also would have become unfit for human habitation. Whether they lived or not, the three men—Alexei Ananenko, Valeri Bezpalov, and Boris Baranov—stilled the wings of a deadly butterfly. Indeed, the entire Chernobyl disaster was the result of poor design and the ineptitude of staff. The long-term result (in addition to the impact on residents of the area) was widespread anxiety towards nuclear plants and bias

against nuclear power, leading to a preference for fossil fuels. Some people have speculated that Chernobyl is responsible for the acceleration of global warming, as countries became unduly slow to adopt nuclear power.

- The Cuban Missile Crisis. We all may owe our lives to a single Russian Navy officer named Vasili Arkhipov, who has been called “the man who saved the world.” During the Cuban Missile Crisis, Arkhipov was stationed on a nuclear-armed submarine near Cuba. American aircraft and ships began using depth charges to signal the submarine that it should surface so it could be identified. With the submarine submerged too deep to monitor radio signals, the crew had no idea what was going on in the world above. The captain, Savitsky, decided the signal meant that war had broken out and he prepared to launch a nuclear torpedo. Everyone agreed with him—except Arkhipov. Had the torpedo launched, nuclear clouds would have hit Moscow, London, East Anglia and Germany, before wiping out half of the British population. The result could have been a worldwide nuclear holocaust, as countries retaliated and the conflict spread. Yet within an overheated underwater room, Arkhipov exercised his veto power and prevented a launch. Without the courage of one man, our world could be unimaginably different.

From these handful of examples, it is clear how fragile the world is, and how dire the effects of tiny events can be on starting conditions.

We like to think we can predict the future and exercise a degree of control over powerful systems such as the weather and the economy. Yet the butterfly effect shows that we cannot. The systems around us are chaotic and entropic, prone to sudden change. For some kinds of systems, we can try to create favorable starting conditions and be mindful of the kinds of catalysts that might act on those conditions – but that’s as far as our power extends. If we think that we can identify every catalyst and control or predict outcomes, we are only setting ourselves up for a fall.

115. Reciprocation Bias

“There are slavish souls who carry their appreciation for favors done them so far that they strangle themselves with the rope of gratitude.”

—Friedrich Nietzsche

If you are like me, whenever receiving a favor, you too feel an immense need, almost an obligation, to pay it back in kind.

If a friend invites you over for dinner, you are almost sure to invite them over to your place for dinner as well. It almost seems as if we were meant to do each other favors and, more important, return them.

Have you ever wondered why?

A large part of the reason is that this behavior seems to have strong evolutionary benefits. It's so pervasive in human culture, it's believed that there is no society that does not feel reciprocation's pull. The archaeologist Richard Leakey believes reciprocation is the foundation on which we have evolved: “We are human because our ancestors learned to share their food and their skills in an honored network of obligation.”

The web of indebtedness created by reciprocation allows for the division of tasks, eases the exchange of goods and services, and helps create interdependencies that bind us into units that are more productive than each of us is on our own. Reciprocation allows one person to give something to another with the expectation that the favor will be returned and the giver will not be taken advantage of.

Throughout human history, reciprocation lowered the cost of transactions, as almost everything begins with one person trusting another. Land could be farmed with one person lending seeds to another. Gifts could be given. Currency could be lent. Aid could be given to the weak. Moreover, reciprocation is not a human concept — it exists in the physical world. Newton's third law is that for every action there is an equal and opposite reaction. You might push on a wall, but the wall pushes back on you.

There is such an advantage to be gained from reciprocation that it's become imprinted onto our subconscious. For example, we teach our kids to invite others they may not like to their birthday parties because our kids were invited to those kids' parties. Deeper still, we negatively label people who violate the rule: untrustworthy, moocher, welsher. Because social sanctions can be tough on those who fail to cooperate, the rule of reciprocity often evokes guilt.

As with most things, however, reciprocation has a darker side. Just as we tend to reciprocate good behavior, sometimes we also pay back bad deeds. One of the most effective game-theory strategies is tit for tat.

“Pay every debt, as if God wrote the bill.”

— Ralph Waldo Emerson

Hate

The reciprocation of bad behavior is best evidenced in wars. Brutality escalates as each side feels obliged to return the violence it experienced from its counterpart. This spiral can lead to more mindlessly destructive behavior, including torture and mass deaths. There are plenty of examples of this negative reciprocation; consider World War II, the Crusades, and the Mongolian invasions led by Genghis Khan.

It might seem that we humans have exclusively caused much suffering in the world in a relatively short period of time. However, the reciprocation rule is overarching — the human species is not the only one capable of extreme cruelty. Charlie Munger believes that reciprocal aggression appears to be more of a rule rather than an exception among other species, too:

One interesting mental exercise is to compare Genghis Khan, who exercised extreme, lethal hostility toward other men, with ants that display extreme, lethal hostility toward members of their own species that are not part of their breeding colony. Genghis looks sweetly lovable when compared to the ants. The ants are more disposed to fight and fight with more extreme cruelty.

If the reciprocation rule is so overpowering, the natural question here would be, is there a way we can still control our response to it?

Munger advises us to train our patience.

The standard antidote to one's overactive hostility is to train oneself to defer reaction. As my smart friend Tom Murphy so frequently says, "You can always tell the man off tomorrow if it is such a good idea."

There's also another way. Because the reciprocation tendency is so extreme, we can reverse the course of events by doing good rather than harm to the other party.

Particularly in WWI, the fighting sometimes paused after a positive feedback loop of less severe damage occurred. Here is how a British staff officer described his surprise about the degree of trust between the British and German soldiers:

[I was] astonished to observe German soldiers walking about within rifle range behind their own line. Our men appeared to take no notice. I privately made up my mind to do away with that sort of thing when we took over; such things should not be allowed. These people evidently did not know there was a war on. Both sides apparently believed in the policy of "live and let live." (Dugdale 1932, p. 94)

Such behavior was not restricted to this one case, but was rather common in trench warfare during the later stages of the war.

And this makes me think that if such things could happen even during a war, there is little doubt that we could improve our relationships by doing a little undeserved good for the other person.

Love

Reciprocation is just as important in breeding love as it is in breeding hate.

Andy Warhol said, in *The Philosophy of Andy Warhol (From A to B and Back Again)*:

Love affairs get too involved, and they're not really worth it. But if, for some reason, you feel that they are, you should put in exactly as much time and energy as the other person. In other words, "I'll pay you if you pay me."

This is the reciprocation tendency at its finest. Truth is, love and marriage would lose much of their allure if there were no reciprocation tendency among partners. By loving, we literally may become loved.

As lovers and spouses, we promise loyalty to our partners and we expect it to be returned. We are encouraged to practice the virtues of marriage in front of not only our partners, but also society. These effects reinforcing each other can be thought of as the fabric of many of today's relationships.

Furthermore, reciprocation not only holds us together, but can also bring us together in the first place. Displaying generosity can be a powerful way to advance a relationship by setting up implicit expectations of compliance from the other person.

Women, in particular, often report on the pressure they feel after receiving expensive gifts or dinners. In *Influence*, professor of psychology Robert Cialdini quotes the words of one of his (female) students:

After learning the hard way, I no longer let a guy I meet in a club buy me a drink because I don't want either of us to feel that I am obligated sexually.

Perhaps the key to genuine relationships lies at least partially in each party being kind without expectations. Indeed, in communal relationships like marriage, friendship, and the parent-child relationship, the accounting is unnecessary, and if you think about it, you'll see that it is hardly ever practiced.

What is exchanged reciprocally instead is the near-unconditional willingness to provide what the other side needs, when it is needed. Still, some symmetry seems to be best; even in close friendships, strong inequalities will eventually make themselves noticed.

Abusing Reciprocity

As with any human tendency, reciprocity holds a great potential for abuse. Charlie Munger recalls how the eccentric hedge-fund manager Victor Niederhoffer managed to get good grades with an impressive course load when he was an undergraduate student at Harvard. Contrary to what one may expect, Niederhoffer was not a very hard-working student. Instead of studying, he liked spending his time playing world-class checkers, gambling in high-stakes card games, and playing amateur-level tennis and professional-level squash. So how did he manage to get those good grades?

Munger explains:

He thought he was up to outsmarting the Harvard Economics Department. And he was. He noticed that the graduate students did most of the boring work that would otherwise go to the professors, and he noticed that because it was so hard to get to be a graduate student at Harvard, they were all very brilliant and organized and hard working, as well as much needed by grateful professors.

And therefore, by custom, and as would be predicted from the psychological force called reciprocity tendency, in a really advanced graduate course, the professors always gave an A. So Victor Niederhoffer signed up for nothing but the most advanced graduate courses in the Harvard Economics Department, and of course, he got A, after A, after A, after A, and was hardly ever near a class. And for a while, some people at Harvard may have thought it had a new prodigy on its hands. That's a ridiculous story, but the scheme will work still.

And Niederhoffer is famous: they call his style "Niederhofferizing the curriculum."

There are cases that are less innocent than Niederhoffer's gaming the system. For example, when a salesman offers us a cup of coffee with cookies, we are likely to be subconsciously tricked into compliance by even such a minor favor, which combines reciprocity and association. Buying can be just as much about the actual experience as it is about acquiring goods at an optimal price, and salesmen know this.

Your Costs Are My Benefits

In our personal expenses, we are the ones suffering from our follies, but an important problem arises when we buy on someone else's behalf. Imagine that you are the purchasing agent for an employer. Now the extra costs that are paid in return for the minor favor you receive are incurred not by you but by your employer.

Gifts and favors tend to create perverse incentives on the purchaser's part and allow the seller to maximize his advantage. Smart employers know this and therefore do not allow their purchasing personnel to accept gifts. Sam Walton is one notable example; he wouldn't let Walmart's purchasing agents accept even a hot dog from a vendor.

The exchange of favors at another's expense is not restricted to purchasing on someone's behalf.

Munger notes that the reciprocation tendency can also be held responsible for some wicked pay dynamics in the boardroom of public companies:

It's incredible the reciprocity that happens when CEOs keep recommending that directors get paid more, and then the directors raise the CEO's pay — it's a big game of pitty pat. And then they hire compensation consultants to make sure no-one else is getting paid more. This is true even if the CEO is a klutz and a little dishonorable. I think the existing system is very bad and my system would work better, but it's not going to happen.

In order to prevent these dynamics, he suggests that the board of directors does not get paid at all.

I think tons of eminent people would serve on boards of companies like Exxon without being paid. The lower courts in England are run by unpaid magistrates. And Harvard is run by boards of people who don't get paid — in fact, they have to pay [in the form of

donations to the school]. I think boards would be better if they were run like Berkshire Hathaway's.

For these same reasons, Munger believes that the reciprocity tendency should be part of the compulsory law curriculum; otherwise, students may unknowingly steer away from representing their clients' best interests. Ignorance of the reciprocation rule may explain why malpractice still occurs even among lawyers with the best intentions. The law schools simply don't know, or care to teach, what Sam Walton knew so well.

The Concession

Besides the obvious doing of favors, there is a more subtle technique that may lure us into reciprocal and cooperative behavior. Rob Cialdini recalls an incident that made him aware of the technique:

I was walking down the street when I was approached by an 11- or 12-year-old boy. He introduced himself and said he was selling tickets to the annual Boy Scouts Circus to be held on the upcoming Saturday night. He asked if I wished to buy any tickets at \$5 apiece. Since one of the last places I wanted to spend Saturday evening was with the Boy Scouts, I declined. "Well," he said, "if you don't want to buy any tickets, how about buying some of our chocolate bars? They're only \$1 each."

Cialdini automatically bought two chocolates and immediately realized that something was wrong:

I knew that to be the case because (a) I do not like chocolate bars; (b) I do like dollars; (c) I was standing there with two of his chocolate bars; and (d) he was walking away with two of my dollars.

After meeting with his research assistants and conducting experiments with a similar setup on his students, Cialdini arrived at a rule that explains this behavior: The person who acts in a certain way toward us is entitled to a similar return action.

[quote]The person who acts in a certain way toward us is entitled to a similar return action.
[/quote]

This rule has two consequences:

1. We feel obliged to repay favors we have received.
2. We feel obliged to make a concession to someone who has made a concession to us.

As Cialdini and his research group reflected, they increasingly saw that the Boy Scout had brought him under the rule. The request to purchase the chocolates was introduced as a concession — a retreat from the request that Cialdini buy some \$5 tickets.

If Cialdini was to live up to the dictates of the reciprocation rule, there had to be a concession on his part. And there was — after all, Cialdini moved from rejection to compliance after the boy had moved from a larger to a smaller request. The remarkable thing, and this is where bias comes in, was that Cialdini was not at all interested in either of the things the boy had offered.

Why would this rule be so important? Because it can lead to a lot of unnecessary trouble. Both Cialdini and Munger believe that a subconscious reciprocation tendency was an important lever that allowed Watergate, one of the biggest political scandals in history, to occur.

Breaking into the Watergate offices of the Democratic party was a plan that was conceived by G. Gordon Liddy, an aggressive subordinate with a questionable reputation. Liddy pulled the same trick on his superiors that the twelve-year-old boy did on Cialdini. The \$250,000 break-in plan was not the first that Liddy proposed — it was a significant concession from the previous two. The first of these plans, for \$1 million, entailed a program that included a specially equipped "chase plane," break-ins, kidnapping and

mugging squads, and a yacht featuring “high-class call girls,” all meant to blackmail the Democratic politicians.

The second plan was a little more modest, at half of the initial price and reductions in the program. After the two initial plans were rejected by his superiors, Liddy submitted the third, “bare bones” plan, which was a little less stupid and cost “a mere” quarter of the initial price.

Do you see what Liddy did there?

Unsurprisingly, his superiors gave in; eventually, the plan was approved and it started the snowball that caused Nixon to resign. As the Watergate example illustrates, an unwatched reciprocation tendency may subtly cause mindless behavior with many extreme or dangerous consequences.

One of the reasons reciprocation can be used so effectively as a device for gaining another’s compliance is that it combines power and subtlety. Especially in its concessionary form, the reciprocation rule often produces a yes response to a request that otherwise would surely have been refused.

I hope that the next time you come across a situation where you feel the need to return a favor, you will think twice about the possible consequences of accepting it in the first place. You may think, for example, that someone offering you a free pen will not influence you at all, but there is an entire human history arguing otherwise. Perhaps Sam Walton’s policy, of not accepting favors at all in matters where impartiality is preferred, is best.

Yet there is some truth to saying that reciprocal behavior also represents the best part of human nature. There are times when successful trade, good friendships, and even romantic relationships develop out of the need to feel symmetrical in our relationships. Indeed, it could well be that the very best parts of our lives lie in relationships of affection in which both we and the other party want to please each other.

116. Complex Adaptive Cities

Complex adaptive systems are hard to understand. Messy and complicated, they cannot be broken down into smaller bits. It would be easier to ignore them, or simply leave them as mysteries. But given that we are living in one such system, it might be more useful to buckle down and sort it out. That way, we can make choices that are aligned with how the world actually operates.

In his book *Diversity and Complexity*, Scott E. Page explains, “Complexity can be loosely thought of as interesting structures and patterns that are not easily described or predicted. Systems that produce complexity consist of diverse rule-following entities whose behaviors are interdependent. Those entities interact over a contact structure or network. In addition, the entities often adapt.”

Understanding complexity is important, because sometimes things are not further reducible. While the premise of Occam’s Razor is that things should be made as simple as possible but not simpler, sometimes there are things that cannot be reduced. There is, in fact, an irreducible minimum. Certain things can be properly contemplated only in all their complicated, interconnected glory.

Take, for example, cities.

[quote]Cities cannot be created for success from the top down by the imposition of simple rules.[/quote]

For those of us who live in cities, we all know what makes a particular neighborhood great. We can get what we need and have the interactions we want, and that’s ultimately because we feel safe there.

But how is this achieved? What magic combination of people and locations, uses and destinations, makes a vibrant, safe neighborhood? Is there a formula for, say, the ratio of houses to businesses, or of children to workers?

No. Cities are complex adaptive systems. They cannot be created for success from the top down by the imposition of simple rules.

In her seminal book *The Death and Life of Great American Cities*, Jane Jacobs approached the city as a complex adaptive system, turned city planning on its head, and likely saved many North American cities by taking them apart and showing that they cannot be reduced to a series of simple behavioral interactions.

Cities fall exactly into the definition of complexity given above by Page. They are full of rule-following humans, cars, and wildlife, the behaviors of which are interdependent on the other entities and respond to feedback.

These components of a city interact over multiple interfaces in a city network and will adapt easily, changing their behavior based on food availability, road closures, or perceived safety. But the city itself cannot be understood by looking at just one of these behaviors.

Jacobs starts with “the kind of problem which cities pose — a problem in handling organized complexity” — and a series of observations about that common, almost innocuous, part of all cities: the sidewalk.

What makes a particular neighborhood safe?

Jacobs argues that there is no one factor but rather a series of them. In order to understand how a city street can be safe, you must examine the full scope of interactions that occur on its sidewalk. “The trust of a city street is formed over time from many, many little public sidewalk contacts.” Nodding to people you know, noticing people you don’t. Recognizing which parent goes with which kid, or whose business seems to be thriving. People create safety.

Given that most of them are strangers to each other, how do they do this? How come these strangers are not all perceived as threats?

Safe streets are streets that are used by many different types of people throughout the 24-hour day. Children, workers, caregivers, tourists, diners — the more people who use the sidewalk, the more eyes that participate in the safety of the street.

Safety on city streets is “kept primarily by an intricate, almost unconscious, network of voluntary controls and standards among the people themselves, and enforced by the people themselves.” Essentially, we all contribute to safety because we all want safety. It increases our chances of survival.

Jacobs brings an amazing eye for observational detail in describing neighborhoods that work and those that don't. In describing sidewalks, she explains that successful, safe neighborhoods are orderly. “But there is nothing simple about that order itself, or the bewildering number of components that go into it. Most of those components are specialized in one way or another. They unite in their joint effect upon the sidewalk, which is not specialized in the least. That is its strength.” For example, restaurant patrons, shopkeepers, loitering teenagers, etc. — some of whom belong to the area and some of whom are transient — all use the sidewalk and in doing so contribute to the interconnected and interdependent relationships that produce the perception of safety on that street. And real safety will follow perceived safety.

To get people participating in this unorganized street safety, you have to have streets that are desirable. “You can't make people use streets they have no reason to use. You can't make people watch streets they do not want to watch.” But Jacobs points out time and again that there is no predictable prescription for how to achieve this mixed use where people are unconsciously invested in the maintenance of safety.

This is where considering the city as a complex adaptive system is most useful.

Each individual component has a part to play, so a top-down imposition of theory that doesn't allow for the unpredictable behavior of each individual is doomed to fail. “Orthodox planning is much imbued with puritanical and Utopian conceptions of how people should spend their free time, and in planning, these moralisms on people's private lives are deeply confused with concepts about the workings of cities.” A large, diverse group of people is not going to conform to only one way of living. And it's the diversity that offers the protection.

For example, a city planner might decide to not have bars in residential neighborhoods.

The noise might keep people up, or there will be a negative moral impact on the children who are exposed to the behavior of loud, obnoxious drunks. But as Jacobs reveals, safe city areas can't be built on the basis of this type of simplistic assumption.

By stretching the use of a street through as many hours of the day as possible, you might create a safer neighborhood. I say “might” because in this complex system, other factors might connect to manifest a different reality.

[quote]Planning that doesn't respect the spectrum of diverse behavior and instead aims to insist on an ideal based on a few simple concepts will hinder the natural ability of a system to adapt.[/quote]

As Scott Page explains, “Creating a complex system from scratch takes skill (or evolution). Therefore, when we see diverse complex systems in the real world, we should not assume that they've been assembled from whole cloth. Far more likely, they've been constructed bit by bit.”

Urban planning that doesn't respect the spectrum of diverse behavior and instead aims to insist on an ideal based on a few simple concepts (fresh air, more public space, large private space) will hinder the natural ability of a city system to adapt in a way that suits the residents. And it is this ability to adapt that is the cornerstone requirement of this type of complex system. Inhibit the adaptive property and you all but ensure the collapse of the system.

As Jacobs articulates:

Under the seeming disorder of the old city, wherever the old city is working successfully, is a marvelous order for maintaining the safety of the streets and the freedom of the city. It is a complex order. Its essence is intricacy of sidewalk use, bringing with it a constant succession of eyes. This order is all composed of movement and change, and although it is life, not art, we may fancifully call it the art form of the city and liken it to the dance — ... to an intricate ballet in which the individual dancers and ensembles all have distinctive parts which miraculously reinforce each other and compose an orderly whole. The ballet of the good city sidewalk never repeats itself from place to place, and in any one place is always replete with new improvisations.

This is the essence of complexity. As Scott Page argues, “Adaptation occurs at the level of individuals or of types. The system itself doesn’t adapt. The parts do; they alter their behaviors leading to system level adaptation.”

Jacobs maintains that “the sight of people attracts still other people.” We feel more secure when we know there are multiple eyes on us, eyes that are concerned only with the immediate function that might affect them and are not therefore invasive.

Our complex behavior as individuals in cities, interacting with various components in any given day, is multiplied by everyone, so a city that produces a safe environment seems to be almost miraculous. But ultimately our behavior is governed by certain rules — not rules that are imposed by theory or external forces, but rules that we all feel are critical to our well-being and success in our city.

Thus, the workings of a desirable city are produced by a multitude of small interactions that have evolved and adapted as they have promoted the existence of the things that most support the desires of individuals.

“The look of things and the way they work are inextricably bound together, and in no place more so than cities,” claims Jacobs. Use is not independent of form. That is why we must understand the system as a whole. No matter how many components and unpredictable potential interactions there are, they are all part of what makes the city function.

As Jacobs concludes, “There is no use wishing it were a simpler problem, because in real life it is not a simpler problem. No matter what you try to do to it, a city park behaves like a problem in organized complexity, and that is what it is. The same is true of all other parts or features of cities. Although the inter-relations of their many factors are complex, there is nothing accidental or irrational about the ways in which these factors affect each other.”

117. The Power of Incentives: The Hidden Forces That Shape Behavior

Incentives are what drive human behavior. Understanding incentives is the key to understanding people. Conversely, failing to recognize the importance of incentives often leads us to make major errors.

“Never, ever, think about something else when you should be thinking about the power of incentives.”

— Charlie Munger

According to Charlie Munger, there are only a few forces more powerful than incentives. In his speech *The Psychology of Human Misjudgment*, he reflects on how the power of incentives never disappoints him:

Well, I think I’ve been in the top 5% of my age cohort all my life in understanding the power of incentives, and all my life I’ve underestimated it. And never a year passes but I get some surprise that pushes my limit a little farther.

Sometimes the solution to a behavior problem is simply to revisit incentives and make sure they align with the desired goal. Munger talks about Federal Express, which is one of his favorite examples of the power of incentives:

The heart and soul of the integrity of the system is that all the packages have to be shifted rapidly in one central location each night. And the system has no integrity if the whole shift can’t be done fast. And Federal Express had one hell of a time getting the thing to work. And they tried moral suasion, they tried everything in the world, and finally somebody got the happy thought that they were paying the night shift by the hour, and that maybe if they paid them by the shift, the system would work better. And lo and behold, that solution worked.

If you’re trying to change a behavior, reason will take you only so far. Reflecting on another example where misaligned incentives hampered the sales of a superior product, Munger said:

Early in the history of Xerox, Joe Wilson, who was then in the government, had to go back to Xerox because he couldn’t understand how their better, new machine was selling so poorly in relation to their older and inferior machine. Of course when he got there, he found out that the commission arrangement with the salesmen gave a tremendous incentive to the inferior machine.

Ignoring incentives almost never works out well. Thinking about the incentives of others is necessary to create win-win relationships.

We can turn to psychology to obtain a more structured and thorough understanding of how incentives shape our actions.

The Science of Reinforcement

The science of reinforcement was furthered by Burrhus Frederic Skinner (usually called B.F. Skinner), a professor of psychology at Harvard from 1958 to 1974.

Skinner, unlike his contemporaries, refused to hypothesize about what happened on the inside (what people or animals thought and felt) and preferred to focus on what we can observe. To him, focusing on how much people ate meant more than focusing on subjective measures, like how hungry people were or how much pleasure they got from eating. He wanted to find out how environmental variables affected behavior, and he believed that behavior is shaped by its consequences.

If we don’t like the consequences of an action we’ve taken, we’re less likely to do it again; if we do like the consequences, we’re more likely to do it again. That assumption is the basis of operant conditioning, “a type of learning in which the strength of a behavior is modified by [its] consequences, such as reward or punishment.” ¹

One of Skinner's most important inventions was the operant conditioning chamber, also known as a "Skinner box," which was used to study the effects of reinforcers on lab animals. The rats in the box had to figure out how to do a task (such as pushing a lever) that would reward them with food. Such an automated system allowed Skinner and thousands of successors to study conditioned behavior in a controlled setting.

What years of studies on reinforcement have revealed is that consistency and timing play important roles in shaping new behaviors. Psychologists argue that the best way for us to learn complex behaviors is via continuous reinforcement, in which the desired behavior is reinforced every time it's performed.

If you want to teach your dog a new trick, for example, it is smart to reward him for every correct response. At the very beginning of the learning curve, your failure to immediately respond to a positive behavior might be misinterpreted as a sign of incorrect behavior from the dog's perspective.

Intermittent reinforcement is reinforcement that is given only some of the times that the desired behavior occurs, and it can be done according to various schedules, some predictable and some not (see "Scheduling Reinforcement," below). Intermittent reinforcement is argued to be the most efficient way to maintain an already learnt behavior. This is due to three reasons.

First, rewarding the behavior takes time away from the behavior's continuation. Paying a worker after each piece is assembled on the assembly line simply does not make sense. Second, intermittent reinforcement is better from an economic perspective. Not only is it cheaper not to reward every instance of a desired behavior, but by making the rewards unpredictable, you trigger excitement and thus get an increase in response without increasing the amount of reinforcement. Intermittent reinforcement is how casinos work; they want people to gamble, but they can't afford to have people win large amounts very often.

Finally, intermittent reinforcement can induce resistance to extinction (stopping the behavior when reinforcement is removed). Consider the example of resistance outlined in the textbook Psychology: Core Concepts:

Imagine two gamblers and two slot machines. One machine inexplicably pays off on every trial and another, a more usual machine, pays on an unpredictable, intermittent schedule. Now, suppose that both devices suddenly stop paying. Which gambler will catch on first? Most of us would probably guess it right:

The one who has been rewarded for each pull of the lever (continuous reinforcement) will quickly notice the change, while the gambler who has won only occasionally (on partial reinforcement) may continue playing unrewarded for a long time.

Scheduling Reinforcement

Intermittent reinforcement can be used on various schedules, each with its own degree of effectiveness and situations to which it can be appropriately applied. Ratio schedules are based on the number of responses (the amount of work done), whereas interval schedules are based on the amount of time spent.

- Fixed-ratio schedules are used when you pay your employees based on the amount of work they do. Fixed-ratio schedules are common in freelancing, where contractors are paid on a piecework basis. Managers like fixed-ratio schedules because the response to reinforcement is usually very high (if you want to get paid, you do the work).
- Variable-ratio schedules are unpredictable because the number of responses between reinforcers varies. Telemarketers, salespeople, and slot machine players are on this schedule because they never know when the next sale or the next big win will occur. Skinner himself demonstrated the power of this schedule by showing that a hungry pigeon would peck a disk 12,000 times an hour while being rewarded

on average for only every 110 pecks. Unsurprisingly, this is the type of reinforcement that normally produces more responses than any other schedule. (Varying the intervals between reinforcers is another way of making reinforcement unpredictable, but if you want people to feel appreciated, this kind of schedule is probably not the one to use.)

- Fixed-interval schedules are the most common type of payment — they reward people for the time spent on a specific task. You might have already guessed that the response rate on this schedule is very low. Even a rat in a Skinner box programmed for a fixed-interval schedule learns that lever presses beyond the required minimum are just a waste of energy. Ironically, the “9-5 job” is a preferred way to reward employees in business.

While the design of scheduling can be a powerful technique for continuing or amplifying a specific behavior, we may still fail to recognize an important aspect of reinforcement — individual preferences for specific rewards.

Experience suggests that survival is propelled by our need for food and water. However, most of us don't live in conditions of extreme scarcity and thus the types of reinforcement appealing to us will differ.

Culture plays an important role in determining effective reinforcers. And what's reinforced shapes culture. Offering tickets to a cricket match might serve as a powerful reward for someone in a country where cricket is a big deal, but would be meaningless to most Americans. Similarly, an air-conditioned office might be a powerful incentive for employees in Indonesia, but won't matter as much to employees in a more temperate area.

What About Punishment?

So far we've talked about positive reinforcement — the carrot, if you will. However, there is also a stick.

There is no doubt that our society relies heavily on threat and punishment as a way to keep ourselves in line. Still, we keep arriving late, forgetting birthdays, and receiving parking fines, even though we know there is the potential to be punished.

There are several reasons that punishment might not be the best way to alter someone's behavior.

First of all, Skinner observed that the power of punishment to suppress behavior usually disappears when the threat of punishment is removed. Indeed, we all refrain from using social networks during work hours, when we know our boss is around, and we similarly adhere to the speed limit when we know we are being watched by a police patrol.

Second, punishment often triggers a fight-or-flight response and renders us aggressive. When punished, we seek to flee from further punishment, and when the escape is blocked, we may become aggressive. This punishment-aggression link may also explain why abusing parents come from abusing families themselves.

Third, punishment inhibits the ability to learn new and better responses. Punishment leads to a variety of responses — such as escape, aggression, and learned helplessness — none of which aid in the subject's learning process. Punishment also fails to show subjects what exactly they must do and instead focuses on what not to do. This is why environments that forgive failure are so important in the learning process.

Finally, punishment is often applied unequally. We are ruled by bias in our assessment of who deserves to be punished. We scold boys more often than girls, physically punish grade-schoolers more often than adults, and control members of racial minorities more often (and more harshly) than whites.

What Should I Do Instead?

There are three alternatives that you can try the next time you feel tempted to punish someone.

The first we already touched upon — extinction. A response will usually diminish or disappear if it ceases to produce the rewards it once did. However, it is important that all possible reinforcements are withheld. This is far more difficult to do in real life than in a lab setting.

What makes it especially difficult is that during the extinction process, organisms tend to look for novel techniques to obtain reinforcement. This means that a whining child will either redouble her efforts or change tactics to regain the parent's attention before ceasing the behavior. In this case, a better extinction strategy is to combine methods by withholding attention after whining occurs and rewarding more desirable behaviors with attention before the whining occurs.

The second alternative is positively reinforcing preferred activities. For example, people who exercise regularly (and enjoy it) might use a daily run as a reward for getting other tasks done. Similarly, young children learn to sit still by being rewarded with occasional permission to run around and make noise. The main principle of this idea is that a preferred activity, such as running around, can be used to reinforce a less preferred activity. This idea is also called the Premack principle.

Finally, prompting and shaping are two actions we can use together to change behavior in an iterative manner. A prompt is a cue or stimulus that encourages the desired behavior. When shaping begins, any approximation of the target response is reinforced. Once you see the approximation occurring regularly, you can make the criterion for the target more strict (the actual behavior has to match the desired behavior more closely), and you continue narrowing the criteria until the specific target behavior is performed. This tactic is often the preferred method of developing a habit gradually and of training animals to perform a specific behavior.

I hope that you are now better equipped to recognize incentives as powerful forces shaping the way we and others behave. The next time you wish someone would change the way they behave, think about changing their incentives.

Like any parent, I experiment with my kids all the time. One of the most effective things I do when one of them has misbehaved is to acknowledge my child's feelings and ask him what he was trying to achieve.

When one kid hits the other, for example, I ask him what he was trying to accomplish.

Usually, the response is "He hit me. (So I hit him back.)" I know this touches on an automatic human response that many adults can't control. Which makes me wonder how I can change my kids' behavior to be more effective.

"So, you were angry and you wanted him to know?"

"Yes."

"People are not for hitting. If you want, I'll help you go tell him why you're angry."

Tensions dissipate. And I'm (hopefully) starting to get my kids thinking about effective and ineffective ways to achieve their goals.

[quote]Punishment works best to prevent actions whereas incentives work best to encourage them.[/quote]

Let's end with an excellent piece of advice that has been given regarding incentives. Here is Charlie Munger, speaking at the University South California commencement:

You do not want to be in a perverse incentive system that's causing you to behave more and more foolishly or worse and worse — incentives are too powerful a control over human cognition or human behavior. If you're in one [of these systems], I don't have a solution for you. You'll have to figure it out for yourself, but it's a significant problem.

118. The Fairness Principle: How the Veil of Ignorance Helps Test Fairness

The Basics

If you could redesign society from scratch, what would it look like?

How would you distribute wealth and power?

Would you make everyone equal or not? How would you define fairness and equality?

And — here's the kicker — what if you had to make those decisions without knowing who you would be in this new society?

“But the nature of man is sufficiently revealed for him to know something of himself and sufficiently veiled to leave much impenetrable darkness, a darkness in which he ever gropes, forever in vain, trying to understand himself.”

— Alexis de Tocqueville, *Democracy in America*

Philosopher John Rawls asked just that in a thought experiment known as “the Veil of Ignorance” in his 1971 book, *Theory of Justice*.

Like many thought experiments, the Veil of Ignorance could never be carried out in the literal sense, nor should it be. Its purpose is to explore ideas about justice, morality, equality, and social status in a structured manner.

The Veil of Ignorance, a component of social contract theory, allows us to test ideas for fairness.

Behind the Veil of Ignorance, no one knows who they are. They lack clues as to their class, their privileges, their disadvantages, or even their personality. They exist as an impartial group, tasked with designing a new society with its own conception of justice.

As a thought experiment, the Veil of Ignorance is powerful because our usual opinions regarding what is just and unjust are informed by our own experiences. We are shaped by our race, gender, class, education, appearance, sexuality, career, family, and so on. On the other side of the Veil of Ignorance, none of that exists. Technically, the resulting society should be a fair one.

In *Ethical School Leadership*, Spencer J. Maxcy writes:

Imagine that you have set for yourself the task of developing a totally new social contract for today's society. How could you do so fairly? Although you could never actually eliminate all of your personal biases and prejudices, you would need to take steps at least to minimize them. Rawls suggests that you imagine yourself in an original position behind a veil of ignorance. Behind this veil, you know nothing of yourself and your natural abilities, or your position in society. You know nothing of your sex, race, nationality, or individual tastes. Behind such a veil of ignorance all individuals are simply specified as rational, free, and morally equal beings. You do know that in the “real world,” however, there will be a wide variety in the natural distribution of natural assets and abilities, and that there will be differences of sex, race, and culture that will distinguish groups of people from each other. “The Fairness Principle: When contemplating a moral action, imagine that you do not know if you will be the moral doer or receiver, and when in doubt err on the side of the other person.”

— Michael Shermer, *The Moral Arc: How Science and Reason Lead Humanity Toward Truth, Justice, and Freedom*

The Purpose of the Veil of Ignorance

Because people behind the Veil of Ignorance do not know who they will be in this new society, any choice they make in structuring that society could either harm them or benefit them.

If they decide men will be superior, for example, they must face the risk that they will be women. If they decide that 10% of the population will be slaves to the others, they cannot be surprised if they find themselves to be slaves. No one wants to be part of a disadvantaged group, so the logical belief is that the Veil of Ignorance would produce a fair, egalitarian society.

Behind the Veil of Ignorance, cognitive biases melt away. The hypothetical people are rational thinkers. They use probabilistic thinking to assess the likelihood of their being affected by any chosen measure. They possess no opinions for which to seek confirmation. Nor do they have any recently learned information to pay undue attention to. The sole incentive they are biased towards is their own self-preservation, which is equivalent to the preservation of the entire group. They cannot stereotype any particular group as they could be members of it. They lack commitment to their prior selves as they do not know who they are.

So, what would these people decide on? According to Rawls, in a fair society all individuals must possess the following:

- Rights and liberties (including the right to vote, the right to hold public office, free speech, free thought, and fair legal treatment)
- Power and opportunities
- Income and wealth sufficient for a good quality of life (Not everyone needs to be rich, but everyone must have enough money to live a comfortable life.)
- The conditions necessary for self-respect

For these conditions to occur, the people behind the Veil of Ignorance must figure out how to achieve what Rawls regards as the two key components of justice:

- Everyone must have the best possible life which does not cause harm to others.
- Everyone must be able to improve their position, and any inequalities must be present solely if they benefit everyone.

However, the people behind the Veil of Ignorance cannot be completely blank slates or it would be impossible for them to make rational decisions. They understand general principles of science, psychology, politics, and economics. Human behavior is no mystery to them. Neither are key economic concepts, such as comparative advantage and supply and demand. Likewise, they comprehend the deleterious impact of social entropy, and they have a desire to create a stable, ordered society. Knowledge of human psychology leads them to be cognizant of the universal desire for happiness and fulfillment. Rawls considered all of this to be the minimum viable knowledge for rational decision-making.

Ways of Understanding the Veil of Ignorance

One way to understand the Veil of Ignorance is to imagine that you are tasked with cutting up a pizza to share with friends. You will be the last person to take a slice. Being of sound mind, you want to get the largest possible share, and the only way to ensure this is to make all the slices the same size. You could cut one huge slice for yourself and a few tiny ones for your friends, but one of them might take the large slice and leave you with a meager share. (Not to mention, your friends won't think very highly of you.)

Another means of appreciating the implications of the Veil of Ignorance is by considering the social structures of certain species of ants. Even though queen ants are able to form colonies alone, they will band together to form stronger, more productive colonies. Once the first group of worker ants reaches maturity, the queens fight to the death until one remains. When they first form a colony, the queen ants are behind a Veil of Ignorance. They do not know if they will be the sole survivor or not. All they know, on an

instinctual level, is that cooperation is beneficial for their species. Like the people behind the Veil of Ignorance, the ants make a decision which, by necessity, is selfless.

The Veil of Ignorance, as a thought experiment, shows us that ignorance is not always detrimental to a society. In some situations, it can create robust social structures. In the animal kingdom, we see many examples of creatures that cooperate even though they do not know if they will suffer or benefit as a result. In a paper entitled "The Many Selves of Social Insects," Queller and Strassmann write of bees:

...social insect colonies are so tightly integrated that they seem to function as single organisms, as a new level of self. The honeybees' celebrated dance about food location is just one instance of how their colonies integrate and act on information that no single individual possesses. Their unity of purpose is underscored by the heroism of workers, whose suicidal stinging attacks protect the single reproducing queen.

We can also consider the Tragedy of the Commons. Introduced by ecologist Garrett Hardin, this mental model states that shared resources will be exploited if no system for fair distribution is implemented. Individuals have no incentive to leave a share of free resources for others. Hardin's classic example is an area of land which everyone in a village is free to use for their cattle. Each person wants to maximize the usefulness of the land, so they put more and more cattle out to graze. Yet the land is finite and at some point will become too depleted to support livestock. If the people behind the Veil of Ignorance had to choose how the common land should be shared, the logical decision would be to give each person an equal part and forbid them from introducing too many cattle.

As N. Gregory Mankiw writes in Principles of Microeconomics:

The Tragedy of the Commons is a story with a general lesson: when one person uses a common resource, he diminishes other people's enjoyment of it. Because of this negative externality, common resources tend to be used excessively. The government can solve the problem by reducing use of the common resource through regulation or taxes. Alternatively, the government can sometimes turn the common resource into a private good.

This lesson has been known for thousands of years. The ancient Greek philosopher Aristotle pointed out the problem with common resources: "What is common to many is taken least care of, for all men have greater regard for what is their own than for what they possess in common with others."

In The Case for Meritocracy, Michael Faust uses other thought experiments to support the Veil of Ignorance:

Let's imagine another version of the thought experiment. If inheritance is so inherently wonderful — such an intrinsic good — then let's collect together all of the inheritable money in the world. We shall now distribute this money in exactly the same way it would be distributed in today's world... but with one radical difference. We are going to distribute it by lottery rather than by family inheritance, i.e., anyone in the world can receive it. So, in these circumstances, how many people who support inheritance would go on supporting it? Note that the government wouldn't be getting the money... just lucky strangers. Would the advocates of inheritance remain as fiercely committed to their cherished principle? Or would the entire concept instantly be exposed for the nonsense it is?

If inheritance were treated as the lottery it is, no one would stand by it.

[...]

In the world of the 1% versus the 99%, no one in the 1% would ever accept a lottery to decide inheritance because there would be a 99% chance they would end up as schmucks, exactly like the rest of us.

And a further surrealistic thought experiment:

Imagine that on a certain day of the year, each person in the world randomly swaps bodies with another person, living anywhere on earth. Well, for the 1%, there's a 99% chance that they will be swapped from heaven to hell. For the 99%, 1% might be swapped from hell to

heaven, while the other 98% will stay the same as before. What kind of constitution would the human race adopt if annual body swapping were a compulsory event?! They would of course choose a fair one.

"In the immutability of their surroundings the foreign shores, the foreign faces, the changing immensity of life, glide past, veiled not by a sense of mystery but by a slightly disdainful ignorance."

— Joseph Conrad, *Heart of Darkness*

The History of Social Contract Theory

Although the Veil of Ignorance was first described by Rawls in 1971, many other philosophers and writers have discussed similar concepts in the past. Philosophers discussed social contract theory as far back as ancient Greece.

In *Crito*, Plato describes a conversation in which Socrates discusses the laws of Athens and how they are responsible for his existence. Finding himself in prison and facing the death penalty, Socrates rejects Crito's suggestion that he should escape. He states that further injustice is not an appropriate response to prior injustice. Crito believes that by refusing to escape, Socrates is aiding his enemies, as well as failing to fulfil his role as a father. But Socrates views the laws of Athens as a single entity that has always protected him. He describes breaking any of the laws as being like injuring a parent. Having lived a long, fulfilling life as a result of the social contract he entered at birth, he has no interest in now turning away from Athenian law. Accepting death is essentially a symbolic act that Socrates intends to use to illustrate rationality and reason to his followers. If he were to escape, he would be acting out of accord with the rest of his life, during which he was always concerned with justice.

Social contract theory is concerned with the laws and norms a society decides on and the obligation individuals have to follow them. Socrates' dialogue with Plato has similarities with the final scene of Arthur Miller's *The Crucible*. At the end of the play, John Proctor is hung for witchcraft despite having the option to confess and avoid death. In continuing to follow the social contract of Salem and not confessing to a crime he obviously did not commit, Proctor believes that his death will redeem his earlier mistakes. We see this in the final dialogue between Reverend Hale and Elizabeth (Proctor's wife):

HALE: Woman, plead with him! [...] Woman! It is pride, it is vanity. [...] Be his helper! What profit him to bleed? Shall the dust praise him? Shall the worms declare his truth? Go to him, take his shame away!

ELIZABETH: [...] He have his goodness now. God forbid I take it from him!

In these two situations, individuals allow themselves to be put to death in the interest of following the social contract they agreed upon by living in their respective societies. Earlier in their lives, neither person knew what their ultimate fate would be. They were essentially behind the Veil of Ignorance when they chose (consciously or unconsciously) to follow the laws enforced by the people around them. Just as the people behind the Veil of Ignorance must accept whatever roles they receive in the new society, Socrates and Proctor followed social contracts. To modern eyes, the decision both men make to abandon their children in the interest of proving a point is not easily defensible.

Immanuel Kant wrote about justice and freedom in the late 1700s. Kant believed that fair laws should not be based on making people happy or reflecting the desire of individual policymakers, but should be based on universal moral principles:

Is it not of the utmost necessity to construct a pure moral philosophy which is completely freed from everything that may be only empirical and thus belong to anthropology? That there must be such a philosophy is self-evident from the common idea of duty and moral laws. Everyone must admit that a law, if it is to hold morally, i.e., as a ground of obligation,

must imply absolute necessity; he must admit that the command, "Then shalt not lie," does not apply to men only, as if other rational beings had no need to observe it. The same is true for all other moral laws properly so called. He must concede that the ground of obligation here must not be sought in the nature of man or in the circumstances in which he is placed, but sought *a priori* solely in the concepts of pure reason, and that every other precept which is in certain respects universal, so far as it leans in the least on empirical grounds (perhaps only in regard to the motive involved), may be called a practical rule but never a moral law.

How We Can Apply This Concept

We can use the Veil of Ignorance to test whether a certain issue is fair.

When my kids are fighting over the last cookie, which happens more often than you'd imagine, I ask them to determine who will spilt the cookie. The other person picks. This is the old playground rule, "you split, I pick." Without this rule, one of them would surely give the other a smaller portion. With it, the halves are as equal as they would be with sensible adults.

When considering whether we should endorse a proposed law or policy, we can ask: if I did not know if this would affect me or not, would I still support it? Those who make big decisions that shape the lives of large numbers of people are almost always those in positions of power. And those in positions of power are almost always members of privileged groups. As Benjamin Franklin once wrote: "Justice will not be served until those who are unaffected are as outraged as those who are."

Laws allowing or prohibiting abortion have typically been made by men, for example. As the issue lacks real significance in their personal lives, they are free to base decisions on their own ideological views, rather than consider what is fair and sane. However, behind the Veil of Ignorance, no one knows their sex. Anyone deciding on abortion laws would have to face the possibility that they themselves will end up as a woman with an unwanted pregnancy.

In *Justice as Fairness: A Restatement*, Rawls writes:

So what better alternative is there than an agreement between citizens themselves reached under conditions that are fair for all?

[...]

[T]hreats of force and coercion, deception and fraud, and so on must be ruled out.

And:

Deep religious and moral conflicts characterize the subjective circumstances of justice.

Those engaged in these conflicts are surely not in general self-interested, but rather, see themselves as defending their basic rights and liberties which secure their legitimate and fundamental interests. Moreover, these conflicts can be the most intractable and deeply divisive, often more so than social and economic ones.

In *Ethics: Studying the Art of Moral Appraisal*, Ronnie Littlejohn explains:

We must have a mechanism by which we can eliminate the arbitrariness and bias of our "situation in life" and insure that our moral standards are justified by the one thing all people share in common: reason. It is the function of the veil of ignorance to remove such bias.

When we have to make decisions that will affect other people, especially disadvantaged groups (such as when a politician decides to cut benefits or a CEO decides to outsource manufacturing to a low-income country), we can use the Veil of Ignorance as a tool for making fair choices.

As Robert F. Kennedy (the younger brother of John F. Kennedy) said in the 1960s:

Few will have the greatness to bend history itself, but each of us can work to change a small portion of events. It is from numberless diverse acts of courage and belief that human history is shaped. Each time a man stands up for an ideal, or acts to improve the

lot of others, or strikes out against injustice, he sends forth a tiny ripple of hope, and crossing each other from a million different centers of energy and daring, those ripples build a current which can sweep down the mightiest walls of oppression and resistance. When we choose to position ourselves behind the Veil of Ignorance, we have a better chance of creating one of those all-important ripples.

119. Power Laws: How Nonlinear Relationships Amplify Results

“The greatest shortcoming of the human race is our inability to understand the exponential function.”

— Albert Allen Bartlett

Defining A Power Law

Consider a person who begins weightlifting for the first time.

During their initial sessions, they can lift only a small amount of weight. But as they invest more time, they find that for each training session, their strength increases a surprising amount.

For a while, they make huge improvements. Eventually, however, their progress slows down. At first, they could increase their strength by as much as 10% per session; now it takes months to improve by even 1%. Perhaps they resort to taking performance-enhancing drugs or training more often. Their motivation is sapped, and they find themselves getting injured, without any real change in the amount of weight they can lift. Now, let's imagine that our frustrated weightlifter decides to take up running instead. Something similar happens. While the first few runs are incredibly difficult, the person's endurance increases rapidly with the passing of each week, until it levels off and diminishing returns set in again.

Both of these situations are examples of *power laws* — a relationship between two things in which a change in one thing can lead to a large change in the other, regardless of the initial quantities. In both of our examples, a small investment of time at the beginning of the endeavor leads to a large increase in performance.

Power laws are interesting because they reveal surprising correlations between disparate factors. As a mental model, power laws are versatile, with numerous applications in different fields of knowledge.

If parts of this post look intimidating to non-mathematicians, bear with us. Understanding the math behind power laws is worthwhile to grasp their many applications. Invest a little time in reading this and reap the value — which is in itself an example of a power-law!

A power law is often represented by an equation with an exponent:

$$Y=MX^B$$

Each letter represents a number. Y is a function (the result); X is the variable (the thing you can change); B is the order of scaling (the exponent), and M is a constant (unchanging).

If M is equal to 1, the equation is then $Y=X^B$. If $B=2$, the equation becomes $Y=X^2$ ($Y=X$ squared). If X is 1, Y is also 1. But if $X=2$, then $Y=4$; if $X=3$, then $Y=9$, and so on. A small change in the value of X leads to a proportionally large change in the value of Y.

$B=1$ is known as the linear scaling law.

To double a cake recipe, you need twice as much flour. To drive twice as far will take twice as long. (Unless you have kids, in which case you need to factor in bathroom breaks that seemingly have little to do with distance.) Linear relationships, in which twice-as-big requires twice-as-much, are simple and intuitive.

Nonlinear relationships are more complicated. In these cases, you don't need twice as much of the original value to get twice the increase in some measurable characteristic. For example, an animal that's twice our size requires only about 75% more food than we do. This means that on a per-unit-of-size basis, larger animals are more energy-efficient than smaller ones. As animals get bigger, the energy required to support each unit decreases. One of the characteristics of a complex system is that the behavior of the system differs from the simple addition of its parts. This characteristic is called emergent behavior. “In many instances,” write Geoffrey West in *Scale: The Universal Laws of Growth, Innovation, Sustainability, and the Pace of Life in Organisms, Cities, Economies, and Companies*, “the

whole seems to take on a life of its own, almost dissociated from the specific characteristics of its individual building blocks.”

This collective outcome, in which a system manifests significantly different characteristics from those resulting from simply adding up all of the contributions of its individual constituent parts, is called an emergent behavior.

When we set out to understand a complex system, our intuition tells us to break it down into its component pieces. But that’s *linear* thinking, and it explains why so much of our thinking about complexity falls short. Small changes in a complex system can cause sudden and large changes. Small changes cause cascades among the connected parts, like knocking over the first domino in a long row.

Let’s return to the example of our hypothetical weightlifter-turned-runner. As they put in more time on the road, constraints will naturally arise on their progress.

Recall our exponential equation: $Y=MX^B$. Try applying it to the runner. (We’re going to simplify running, but stick with it.)

Y is the distance the runner can run before becoming exhausted. That’s what we’re trying to calculate. M, the constant, represents their running ability: some combination of their natural endowment and their training history. (Think of it this way: Olympic champion Usain Bolt has a high M; film director Woody Allen has a low M.)

That leaves us with the final term: X^B . The variable X represents the thing we have control over: in this case, our training mileage. If B, the exponent, is between 0 and 1, then the relationship between X and Y— between training mileage and endurance — becomes progressively less proportional. All it takes is plugging in a few numbers to see the effect. Let’s set M to 1 for the sake of simplicity. If $B=0.5$ and $X=4$, then $Y=2$. Four miles on the road gives the athlete the ability to run two miles at a clip.

Increase X to 16, and Y increases only to 4. The runner has to put in four times the road mileage to merely double their running endurance.

Here’s the kicker: With both running and weightlifting, as we increase X, *we’re likely to see the exponent, B, decline!* Quadrupling our training mileage from 16 to 64 miles is unlikely to double our endurance again. It might take a 10x increase in mileage to do that.

Eventually, the ratio of training mileage to endurance will become nearly infinite.

We know this state, of course, as diminishing returns: the point where more input yields progressively less output. Not only is the relationship between training mileage and endurance not linear to begin with, but it also gets *less* linear as we increase our training.

And what about negative exponents?

It gets even more interesting. If $B=-0.5$ and $X=4$, then $Y=0.5$. Four miles on the road gets us a half-mile of endurance. If X is increased to 16, Y declines to 0.25. More training, *less* endurance! This is akin to someone putting in way too much mileage, way too soon: the training is less than useful as injuries pile up.

With negative numbers, the more X increases, the more Y *shrinks*. This relationship is known as an *inverse* power law. $B=-2$, for example, is known as the *inverse square law* and is an important equation in physics.

The relationship between gravity and distance follows an inverse power law. G is the gravitational constant; it’s the constant in Newton’s law of gravitation, relating gravity to the masses and separation of particles, equal to:

$$6.67 \times 10^{-11} \text{ N m}^2 \text{ kg}^{-2}$$

Any force radiating from a single point — including heat, light intensity, and magnetic and electrical forces — follows the inverse square law. At 1m away from a fire, 4 times as much heat is felt as at 2m, and so on.

Higher-Order Power Laws

When B is a positive integer (a whole number larger than zero), there are names for the power laws.

When B is equal to 1, we have a linear relationship, as we discussed above. This is also known as a first-order power law.

Things really get interesting after that.

When B is 2, we have a second-order power law. A great example of this is kinetic energy.

Kinetic energy = $\frac{1}{2} mv^2$

When B is 3, we have a third-order power law. An example of this is the power converted from the wind into rotational energy.

Power Available = $\frac{1}{2} (\text{Air Density}) (\pi r^2) (\text{Windspeed}^3) (\text{Power Coefficient})$

(There is a natural limit here. Albert Betz concluded in 1919 that wind turbines cannot convert more than 59.3% of the kinetic energy of the wind into mechanical energy. This number is called the Betz Limit and represents the power coefficient above.)[1]

The law of heat radiation is a fourth-order power law. Derived first by the Austrian physicist Josef Stefan in 1879 and separately by Austrian physicist Ludwig Boltzmann, the law works like this: the radiant heat energy emitted from a unit area in one second is equal to the constant of proportionality (the Stefan-Boltzmann constant) times the absolute temperature to the fourth power.[2]

There is only one power-law with a variable exponent, and it's considered to be one of the most powerful forces in the universe. It's also the most misunderstood. We call it compounding. The formula looks like this:

Future Value = $(\text{Present Value})(1+i)^n$

where i is the interest rate, and n is the number of years.

Unlike in the other equations, the relationship between X and Y is potentially limitless. As long as B is positive, Y will increase as X does.

Non-integer power laws (where B is a fraction, as with our running example above) are also of great use to physicists. Formulas in which $B=0.5$ are common.

Imagine a car driving at a certain speed. A non-integer power law applies. V is the speed of the car, P is the petrol burnt per second to reach that speed, and A is the air resistance. For the car to go twice as fast, it must use 4 times as much petrol, and to go 3 times as fast, it must use 9 times as much petrol. Air resistance increases as speed increases, and that is why faster cars use such ridiculous amounts of petrol. It might seem logical to think that a car going from 40 miles an hour to 50 miles an hour would use a quarter more fuel. That is incorrect, though, because the relationship between air resistance and speed is itself a power law.

Another instance of a power law is the area of a square. Double the length of two parallel sides and the area quadruples. Do the same for a 3D cube, and the area increases by a factor of eight. It doesn't matter if the length of the square went from 1cm to 2cm, or from 100m to 200m; the area still quadruples. We are all familiar with second-order (or square) power laws. This name comes from squares since the relationship between length and area reflects the way second-order power laws change a number. Third-order (or cubic) power laws are likewise named due to their relationship to cubes.

Using Power Laws in Our Lives

Now that we've gotten through the complicated part let's take a look at how power laws crop up in many fields of knowledge. Most careers involve an understanding of them, even if it might not be so obvious.

"What's the most powerful force in the universe? Compound interest. It builds on itself. Over time, a small amount of money becomes a large amount of money. Persistence is similar. A little bit improves performance, which encourages greater persistence, which improves persistence even more. And on and on it goes."

— Daniel H. Pink, *The Adventures of Johnny Bunko*
The Power Behind Compounding

Compounding is one of our most important mental models and is absolutely vital to understand for investing, personal development, learning, and other crucial areas of life. In economics, we calculate compound interest by using an equation with these variables: P is the original sum of money. P' is the resulting sum of money, r is the annual interest rate, n is the compounding frequency, and t is the length of time. Using an equation, we can illustrate the power of compounding.

If a person deposits \$1000 in a bank for five years, at a quarterly interest rate of 4%, the equation becomes this:

Future Value = Present Value * ((1 + Quarterly Interest Rate) ^ Number of Quarters)

This formula can be used to calculate how much money will be in the account after five years. The answer is \$2,220.20.

Compound interest is a power law because the relationship between the amount of time a sum of money is left in an account and the amount accumulated at the end is non-linear.

In *A Random Walk Down Wall Street*, Burton Malkiel gives the example of two brothers, William and James. Beginning at age 20 and stopping at age 40, William invests \$4,000 per year. Meanwhile, James invests the same amount per year between the ages of 40 and 65. By the time William is 65, he has invested less money than his brother but has allowed it to compound for 25 years. As a result, when both brothers retire, William has 600% more money than James — a gap of \$2 million. One of the smartest financial choices we can make is to start saving as early as possible: by harnessing power laws, we increase the exponent as much as possible.

Compound interest can help us achieve financial freedom and wealth, without the need for a large annual income. Members of the financial independence movement (such as the blogger Mr. Money Mustache) are living examples of how we can apply power laws to our lives.

As far back as the 1800s, Robert G. Ingersoll emphasized the importance of compound interest:

One dollar at compound interest, at twenty-four per cent., for one hundred years, would produce a sum equal to our national debt. Interest eats night and day, and the more it eats the hungrier it grows. The farmer in debt, lying awake at night, can, if he listens, hear it gnaw. If he owes nothing, he can hear his corn grow. Get out of debt as soon as possible. You have supported idle avarice and lazy economy long enough.

Compounding can apply to areas beyond finance — personal development, health, learning, relationships, and more. For each area, a small input can lead to large output, and the results build upon themselves.

Nonlinear Language Learning

When we learn a new language, it's always a good idea to start by learning the 100 or so most used words.

In all known languages, a small percentage of words make up the majority of usage. This is known as Zipf's law, after George Kingsley Zipf, who first identified the phenomenon.

The most used word in a language may make up as much as 7% of all words used, while the second-most-used word is used half as much, and so on. As few as 135 words can together form half of a language (as used by native speakers).

Why Zipf's law holds true is unknown, although the concept is logical. Many languages include a large number of specialist terms that are rarely needed (including legal or anatomy terms). A small change in the frequency ranking of a word means a huge change in its usefulness.

Understanding Zipf's law is a central component of accelerated language learning. Each new word we learn from the most common 100 words will have a huge impact on our ability to communicate. As we learn less-common words, diminishing returns set in. If each word in a language were listed in order of frequency of usage, the further we moved down the list, the less useful a word would be.

Power Laws in Business, Explained by Peter Thiel

Peter Thiel, the founder of PayPal (as well as an early investor in Facebook and Palantir), considers power laws to be a crucial concept for all businesspeople to understand. In his fantastic book, *Zero to One*, Thiel writes:

Indeed, the single most powerful pattern I have noticed is that successful people find value in unexpected places, and they do this by thinking about business from first principles instead of formulas.

And:

In 1906, economist Vilfredo Pareto discovered what became the “Pareto Principle,” or the 80-20 rule, when he noticed that 20% of the people owned 80% of the land in Italy—a phenomenon that he found just as natural as the fact that 20% of the peapods in his garden produced 80% of the peas. This extraordinarily stark pattern, when a small few radically outstrip all rivals, surrounds us everywhere in the natural and social world. The most destructive earthquakes are many times more powerful than all smaller earthquakes combined. The biggest cities dwarf all mere towns put together. And monopoly businesses capture more value than millions of undifferentiated competitors. Whatever Einstein did or didn’t say, the power law—so named because exponential equations describe severely unequal distributions—is the law of the universe. It defines our surroundings so completely that we usually don’t even see it.

... [I]n venture capital, where investors try to profit from exponential growth in early-stage companies, a few companies attain exponentially greater value than all others. ... [W]e don’t live in a normal world; we live under a power law.

... The biggest secret in venture capital is that the best investment in a successful fund equals or outperforms the entire rest of the fund combined.

This implies two very strange rules for VCs. First, only invest in companies that have the potential to return the value of the entire fund. ... This leads to rule number two: because rule number one is so restrictive, there can’t be any other rules.

...[L]ife is not a portfolio: not for a startup founder, and not for any individual. An entrepreneur cannot “diversify” herself; you cannot run dozens of companies at the same time and then hope that one of them works out well. Less obvious but just as important, an individual cannot diversify his own life by keeping dozens of equally possible careers in ready reserve.

Thiel teaches a class called Startup at Stanford, where he hammers home the value of understanding power laws. In his class, he imparts copious wisdom. From Blake Masters’ notes on Class 7:

Consider a prototypical successful venture fund. A number of investments go to zero over a period of time. Those tend to happen earlier rather than later. The investments that succeed do so on some sort of exponential curve. Sum it over the life of a portfolio and you get a J curve. Early investments fail. You have to pay management fees. But then the exponential growth takes place, at least in theory. Since you start out underwater, the big question is when you make it above the water line. A lot of funds never get there.

To answer that big question you have to ask another: what does the distribution of returns in [a] venture fund look like? The naïve response is just to rank companies from best to worst according to their return in multiple of dollars invested. People tend to group investments into three buckets. The bad companies go to zero. The mediocre ones do maybe 1x, so you don’t lose much or gain much. And then the great companies do maybe 3-10x.

But that model misses the key insight that actual returns are incredibly skewed. The more a VC understands this skew pattern, the better the VC. Bad VCs tend to think the dashed line is flat, i.e. that all companies are created equal, and some just fail, spin wheels, or grow. In reality you get a power law distribution.

Thiel explains how investors can apply the mental model of power laws (more from Masters' notes on Class 7):

...Given a big power law distribution, you want to be fairly concentrated. ... There just aren't that many businesses that you can have the requisite high degree of conviction about. A better model is to invest in maybe 7 or 8 promising companies from which you think you can get a 10x return. ...

Despite being rooted in middle school math, exponential thinking is hard. We live in a world where we normally don't experience anything exponentially. Our general life experience is pretty linear. We vastly underestimate exponential things.

He also cautions against over-relying on power laws as a strategy (an assertion that should be kept in mind for all mental models). From Masters' notes:

One shouldn't be mechanical about this heuristic, or treat it as some immutable investment strategy. But it actually checks out pretty well, so at the very least it compels you to think about power law distribution.

Understanding exponents and power law distributions isn't just about understanding VC. There are important personal applications too. Many things, such as key life decisions or starting businesses, also result in similar distributions.

Thiel then explains why founders should focus on one key revenue stream, rather than trying to build multiple equal ones:

Even within an individual business, there is probably a sort of power law as to what's going to drive it. It's troubling if a startup insists that it's going to make money in many different ways. The power law distribution on revenues says that one source of revenue will dominate everything else.

For example, if you're an entrepreneur who opens a coffee shop, you'll have a lot of ways you can make money. You can sell coffee, cakes, paintings, merchandise, and more. But each of those things will not contribute to your success in an equal way. While there is value in the discovery process, once you've found the variable that matters most, you should place more time on that one and less on the others. The importance of finding this variable cannot be overstated.

He also acknowledges that power laws are one of the great secrets of investing success. From Masters' notes on Class 11:

On one level, the anti-competition, power law, and distribution secrets are all secrets about nature. But they're also secrets hidden by people. That is crucial to remember. Suppose you're doing an experiment in a lab. You're trying to figure out a natural secret. But every night another person comes into the lab and messes with your results. You won't understand what's going on if you confine your thinking to the nature side of things. It's not enough to find an interesting experiment and try to do it. You have to understand the human piece too.

... We know that, per the power law secret, companies are not evenly distributed. The distribution tends to be bimodal; there are some great ones, and then there are a lot of ones that don't really work at all. But understanding this isn't enough. There is a big difference between understanding the power law secret in theory and being able to apply it in practice.

The key to all mental models is knowing the facts and being able to use the concept. As George Box said, "all models are false but some are useful." Once we grasp the basics, the best next step is to start figuring out how to apply it.

The metaphor of an unseen person sabotaging laboratory results is an excellent metaphor for how cognitive biases and shortcuts cloud our judgment.

Natural Power Laws

Anyone who has kept a lot of pets will have noticed the link between an animal's size and its lifespan. Small animals, like mice and hamsters, tend to live for a year or two. Larger

ones, like dogs and cats, can live to 10-20 years, or even older in rare cases. Scaling up, even more, some whales can live for 200 years. This comes down to power laws. Biologists have found clear links between an animal's size and its metabolism. Kleiber's law (identified by Max Kleiber) states that an animal's metabolic rate increases at three-fourths of the power of the animal's weight (mass). If an average rabbit (2 kg) weighs one hundred times as much as an average mouse (20g), the rabbit's metabolic rate will be 32 times the mouse's. In other words, the rabbit's structure is more efficient. It all comes down to the geometry behind their mass.

This leads us to another biological power law: Smaller animals require more energy per gram of body weight, meaning that mice eat around half their body weight in dense foods each day. The reason is that, in terms of the percentage of mass, larger animals have more structure (bones, etc.) and fewer reserves (fat stores).

Research has illustrated how power laws apply to blood circulation in animals. The end units through which oxygen, water, and nutrients enter cells from the bloodstream are the same size in all animals. Only the number per animal varies. The relationship between the total area of these units and the size of the animal is a third-order power law. The distance blood travels to enter cells, and the actual volume of blood is also subject to power laws.

The Law of Diminishing Returns

As we have seen, a small change in one area can lead to a huge change in another. However, past a certain point, diminishing returns set in and more is worse. Working an hour extra per day might mean more gets done, whereas working three extra hours is likely to lead to less getting done due to exhaustion. Going from a sedentary lifestyle to running two days a week may result in greatly improved health, but stepping up to seven days a week will cause injuries. Overzealousness can turn a positive exponent into a negative exponent. For a busy restaurant, hiring an extra chef will mean that more people can be served, but hiring two new chefs might spoil the proverbial broth.

Perhaps the most underappreciated diminishing return, the one we never want to end up on the wrong side of, is the one between money and happiness.

In *David and Goliath*, Malcolm Gladwell discusses how diminishing returns relate to family incomes. Most people assume that the more money they make, the happier they and their families will be. This is true — up to a point. An income that's too low to meet basic needs makes people miserable, leading to far more physical and mental health problems. A person who goes from earning \$30,000 a year to earning \$40,000 is likely to experience a dramatic boost in happiness. However, going from \$100,000 to \$110,000 leads to a negligible change in well-being.

Gladwell writes:

The scholars who research happiness suggest that more money stops making people happier at a family income of around seventy-five thousand dollars a year. After that, what economists call "diminishing marginal returns" sets in. If your family makes seventy-five thousand and your neighbor makes a hundred thousand, that extra twenty-five thousand a year means that your neighbor can drive a nicer car and go out to eat slightly more often. But it doesn't make your neighbor happier than you, or better equipped to do the thousands of small and large things that make for being a good parent.

120. The Code of Hammurabi: The Best Rule To Manage Risk

Almost 4,000 years ago, King Hammurabi of Babylon, Mesopotamia, laid out one of the first sets of laws.

Hammurabi's Code is among the oldest translatable writings. It consists of 282 laws, most concerning punishment. Each law takes into account the perpetrator's status. The code also includes the earliest known construction laws, designed to align the incentives of builder and occupant to ensure that builders created safe homes:

- 229. *If a builder builds a house for a man and does not make its construction firm, and the house which he has built collapses and causes the death of the owner of the house, that builder shall be put to death.*
- 230. *If it causes the death of the son of the owner of the house, they shall put to death a son of that builder.*
- 231. *If it causes the death of a slave of the owner of the house, he shall give to the owner of the house a slave of equal value.*
- 232. *If it destroys property, he shall restore whatever it destroyed, and because he did not make the house which he builds firm and it collapsed, he shall rebuild the house which collapsed at his own expense.*
- 233. *If a builder builds a house for a man and does not make its construction meet the requirements and a wall falls in, that builder shall strengthen the wall at his own expense.*

Hammurabi became ruler of Babylon in 1792 BC and held the position for 43 years. In the era of city-states, Hammurabi grew his modest kingdom (somewhere between 60 and 160 square kilometers) by conquering several neighboring states. Satisfied, then, with the size of the area he controlled, Hammurabi settled down to rule his people.

"This world of ours appears to be separated by a slight and precarious margin of safety from a most singular and unexpected danger."

— Arthur Conan Doyle

Hammurabi was a fair leader (from the little we know about him) and concerned with the well-being of his people. He transformed the area, ordering the construction of irrigation ditches to improve agricultural productivity, as well as supplying cities with protective walls and fortresses. Hammurabi also renovated temples and religious sites.

By today's standards, Hammurabi was a dictator. Far from abusing his power, however, he considered himself the "shepherd" of his people. Although the Babylonians kept slaves, they too had rights. Slaves could marry other people of any status, start businesses, and purchase their freedom, and they were protected from mistreatment.

At first glance, it might seem as if we have little to learn from Hammurabi. I mean, why bother learning about the ancient Babylonians? They were just barbaric farmers, right? It seems we're not as different as it appears. Our modern beliefs are not separate from those of people in Hammurabi's time; they are a continuation of them. Early legal codes are the ancestors of the ones we now put our faith in.

Whether a country is a dictatorship or democracy, one of the keys to any effective legal system is the ability for anyone to understand its laws. We're showing cracks in ours and we can learn from the simplicity of Hammurabi's Code, which concerned itself with practical justice and not lofty principles. To even call it a set of laws is misleading. The ancient Babylonians did not appear to have an equivalent term.

Three important concepts are implicit in Hammurabi's Code: reciprocity, accountability, and incentives.

We have no figures for how often Babylonian houses fell down before and after the implementation of the Code. We have no idea how many (if any) people were put to death as a result of failing to adhere to Hammurabi's construction laws. But we do know that human self-preservation instincts are strong. More than strong, they underlie most of our behavior. Wanting to avoid death is the most powerful incentive we have. If we assume that people felt and thought the same way 4000 years ago, we can guess at the impact of the Code.

Imagine yourself as a Babylonian builder. Each time you construct a house, there is a risk it will collapse if you make any mistakes. So, what do you do? You allow for the widest possible margin of safety. You plan for any potential risks. You don't cut corners or try to save a little bit of money. No matter what, you are not going to allow any known flaws in the construction. It wouldn't be worth it. You want to walk away certain that the house is solid.

Now contrast that with modern engineers or builders.

They don't have much skin in the game. The worst they face if they cause a death is a fine. We saw this in Hurricane Katrina — 1600 people died due to flooding caused in part by the poor design of hurricane protection systems in New Orleans. Hindsight analysis showed that the city's floodwalls, levees, pumps, and gates were ill designed and maintained. The death toll was worse than it would otherwise have been. And yet, no one was held accountable.

Hurricane Katrina is regarded as a disaster that was part natural and part man-made. In recent months, in the Grenfell Tower fire in London, we saw the effects of negligent construction. At least 80 people died in a blaze that is believed to have started accidentally but that, according to expert analysis, was accelerated by the conscious use of cheap building materials that had failed safety tests.

The portions of Hammurabi's Code that deal with construction laws, as brutal as they are (and as uncertain as we are of their short-term effects) illustrate an important concept: margins of safety. When we construct a system, ensuring that it can handle the expected pressures is insufficient.

A Babylonian builder would not have been content to make a house that was strong enough to handle just the anticipated stressors. A single Black Swan event — such as abnormal weather — could cause its collapse and in turn the builder's own death, so builders had to allow for a generous margin of safety. The larger the better. In 59 mph winds, we do not want to be in a house built to withstand 60 mph winds.

But our current financial systems do not incentivize people to create wide margins of safety. Instead, they do the opposite — they encourage dangerous risk-taking.

Nassim Taleb referred to Hammurabi's Code in a *New York Times* opinion piece in which he described a way to prevent bankers from threatening the public well-being. His solution? Stop offering bonuses for the risky behavior of people who will not be the ones paying the price if the outcome is bad. Taleb wrote:

...it's time for a fundamental reform: Any person who works for a company that, regardless of its current financial health, would require a taxpayer-financed bailout if it failed should not get a bonus, ever. In fact, all pay at systemically important financial institutions — big banks, but also some insurance companies and even huge hedge funds — should be strictly regulated.

The issue, in Taleb's opinion, is not the usual complaint of income inequality or overpay. Instead, he views bonuses as asymmetric incentives. They reward risks but do not punish the subsequent mistakes that cause "hidden risks to accumulate in the financial system and become a catalyst for disaster." It's a case of "heads, I win; tails, you lose."

Bonuses encourage bankers to ignore the potential for Black Swan events, with the 2008 financial crisis being a prime (or rather, subprime) example. Rather than ignoring these events, banks should seek to minimize the harm caused.

Some career fields have a strict system of incentives and disincentives, both official and unofficial. Doctors get promotions and respect if they do their jobs well, and risk heavy penalties for medical malpractice. With the exception of experiments in which patients are fully informed of and consent to the risks, doctors don't get a free pass for taking risks that cause harm to patients.

The same goes for military and security personnel. As Taleb wrote, "we trust the military and homeland security personnel with our lives, yet we don't give them lavish bonuses. They get promotions and the honor of a job well done if they succeed, and the severe disincentive of shame if they fail."

Hammurabi and his advisors were unconcerned with complex laws and legalese. Instead, they wanted the Code to produce results and to be understandable by everyone. And Hammurabi understood how incentives work — a lesson we'd be well served to learn. When you align incentives of everyone in both positive and negative ways, you create a system that takes care of itself. Taleb describes Law 229 of Hammurabi's Code as "the best risk-management rule ever." Although barbaric to modern eyes, it took into account certain truisms. Builders typically know more about construction than their clients do and can take shortcuts in ways that aren't obvious. After completing construction, a builder can walk away with a little extra profit, while the hapless client is unknowingly left with an unsafe house.

The little extra profit that builders can generate is analogous to the bonus system in some of today's industries. It rewards those who take unwise risks, trick their customers, and harm other people for their own benefit. Hammurabi's system had the opposite effect; it united the interests of the person getting paid and the person paying. Rather than the builder being motivated to earn as much profit as possible and the homeowner being motivated to get a safe house, they both shared the latter goal.

The Code illustrates the efficacy of using self-preservation as an incentive. We feel safer in airplanes that are flown by a person and not by a machine because, in part, we believe that pilots want to protect their own lives along with ours.

When we lack an incentive to protect ourselves, we are far more likely to risk the safety of other people. This is why bankers are willing to harm their customers if it means the bankers get substantial bonuses. This is why companies that market harmful products, such as fast food and tobacco, are content to play down the risks. Or why the British initiative to reduce the population of Indian cobras by compensating those who caught the snakes had the opposite effect. Or why Wells Fargo employees opened millions of fake accounts to reach sales targets.

Incentives backfire when there are no negative consequences for those who exploit them. External incentives are based on extrinsic motivation, which easily goes awry.

When we have real skin in the game—when we have upsides and downsides—we care about outcomes in a way that we wouldn't otherwise. We act in a different way. We take our time. We use second-order thinking and inversion. We look for evidence or a way to disprove it.

Four thousand years ago, the Babylonians understood the power of incentives, yet we seem to have since forgotten about the flaws in human nature that make it difficult to resist temptation.

121. Complexity Bias: Why We Prefer Complicated to Simple

Complexity bias is a logical fallacy that leads us to give undue credence to complex concepts.

Faced with two competing hypotheses, we are likely to choose the most complex one. That's usually the option with the most assumptions and regressions. As a result, when we need to solve a problem, we may ignore simple solutions — thinking “that will never work” — and instead favor complex ones.

To understand complexity bias, we need first to establish the meaning of three key terms associated with it: complexity, simplicity, and chaos.

The Cambridge Dictionary defines complexity as “the state of having many parts and being difficult to understand or find an answer to.” The definition of simplicity is the inverse: “something [that] is easy to understand or do.” Chaos is defined as “a state of total confusion with no order.”

“Life is really simple, but we insist on making it complicated.”

— Confucius

Complex systems contain individual parts that combine to form a collective that often can't be predicted from its components. Consider humans. We are complex systems. We're made of about 100 trillion cells and yet we are so much more than the aggregation of our cells. You'd never predict what we're like or who we are from looking at our cells.

Complexity bias is our tendency to look at something that is easy to understand, or look at it when we are in a state of confusion, and view it as having many parts that are difficult to understand.

We often find it easier to face a complex problem than a simple one.

A person who feels tired all the time might insist that their doctor check their iron levels while ignoring the fact that they are unambiguously sleep deprived. Someone experiencing financial difficulties may stress over the technicalities of their telephone bill while ignoring the large sums of money they spend on cocktails.

Marketers make frequent use of complexity bias.

They do this by incorporating confusing language or insignificant details into product packaging or sales copy. Most people who buy “ammonia-free” hair dye, or a face cream which “contains peptides,” don't fully understand the claims. Terms like these often mean very little, but we see them and imagine that they signify a product that's superior to alternatives.

How many of you know what probiotics really are and how they interact with gut flora?

Meanwhile, we may also see complexity where only chaos exists. This tendency manifests in many forms, such as conspiracy theories, superstition, folklore, and logical fallacies. The distinction between complexity and chaos is not a semantic one. When we imagine that something chaotic is in fact complex, we are seeing it as having an order and more predictability than is warranted. In fact, there is no real order, and prediction is incredibly difficult at best.

Complexity bias is interesting because the majority of cognitive biases occur in order to save mental energy. For example, confirmation bias enables us to avoid the effort associated with updating our beliefs. We stick to our existing opinions and ignore information that contradicts them. Availability bias is a means of avoiding the effort of considering everything we know about a topic. It may seem like the opposite is true, but complexity bias is, in fact, another cognitive shortcut. By opting for impenetrable solutions, we sidestep the need to understand. Of the fight-or-flight responses, complexity bias is the flight response. It is a means of turning away from a problem or concept and labeling it as too confusing. If you think something is harder than it is, you surrender your responsibility to understand it.

“Most geniuses—especially those who lead others—prosper not by deconstructing intricate complexities but by exploiting unrecognized simplicities.”

— Andy Benoit

Faced with too much information on a particular topic or task, we see it as more complex than it is. Often, understanding the fundamentals will get us most of the way there. Software developers often find that 90% of the code for a project takes about half the allocated time. The remaining 10% takes the other half. Writing — and any other sort of creative work — is much the same. When we succumb to complexity bias, we are focusing too hard on the tricky 10% and ignoring the easy 90%.

Research has revealed our inherent bias towards complexity.

In a 1989 paper entitled “Sensible reasoning in two tasks: Rule discovery and hypothesis evaluation,” Hilary F. Farris and Russell Revlin evaluated the topic. In one study, participants were asked to establish an arithmetic rule. They received a set of three numbers (such as 2, 4, 6) and tried to generate a hypothesis by asking the experimenter if other number sequences conformed to the rule. Farris and Revlin wrote, “This task is analogous to one faced by scientists, with the seed triple functioning as an initiating observation, and the act of generating the triple is equivalent to performing an experiment.” The actual rule was simple: list any three ascending numbers.

The participants could have said anything from “1, 2, 3” to “3, 7, 99” and been correct. It should have been easy for the participants to guess this, but most of them didn’t. Instead, they came up with complex rules for the sequences. (Also see [Falsification of Your Best Loved Ideas](#).)

A [paper](#) by Helena Matute looked at how intermittent reinforcement leads people to see complexity in chaos. Three groups of participants were placed in rooms and told that a loud noise would play from time to time. The volume, length, and pattern of the sound were identical for each group. Group 1 (Control) was told to sit and listen to the noises. Group 2 (Escape) was told that there was a specific action they could take to stop the noises. Group 3 (Yoked) was told the same as Group 2, but in their case, there was actually nothing they could do.

Matute wrote:

Yoked participants received the same pattern and duration of tones that had been produced by their counterparts in the Escape group. The amount of noise received by Yoked and Control subjects depends only on the ability of the Escape subjects to terminate the tones. The critical factor is that Yoked subjects do not have control over reinforcement (noise termination) whereas Escape subjects do, and Control subjects are presumably not affected by this variable.

The result? Not one member of the Yoked group realized that they had no control over the sounds. Many members came to repeat particular patterns of “superstitious” behavior. Indeed, the Yoked and Escape groups had very similar perceptions of task controllability. Faced with randomness, the participants saw complexity.

Does that mean the participants were stupid? Not at all. We all exhibit the same superstitious behavior when we believe we can influence chaotic or simple systems.

Funnily enough, animal studies have revealed much the same. In particular, consider B.F. Skinner’s well-known research on the effects of random rewards on pigeons. Skinner placed hungry pigeons in cages equipped with a random-food-delivery mechanism. Over time, the pigeons came to believe that their behavior affected the food delivery. Skinner described this as a form of superstition. One bird spun in counterclockwise circles. Another butted its head against a corner of the cage. Other birds swung or bobbed their heads in specific ways. Although there is some debate as to whether “superstition” is an appropriate

term to apply to birds, Skinner's research shed light on the human tendency to see things as being more complex than they actually are.

Skinner wrote (in "'Superstition' in the Pigeon," *Journal of Experimental Psychology*, 38): *The bird behaves as if there were a causal relation between its behavior and the presentation of food, although such a relation is lacking. There are many analogies in human behavior. Rituals for changing one's fortune at cards are good examples. A few accidental connections between a ritual and favorable consequences suffice to set up and maintain the behavior in spite of many unreinforced instances. The bowler who has released a ball down the alley but continues to behave as if he were controlling it by twisting and turning his arm and shoulder is another case in point. These behaviors have, of course, no real effect upon one's luck or upon a ball half way down an alley, just as in the present case the food would appear as often if the pigeon did nothing—or, more strictly speaking, did something else.*

The world around us is a chaotic, entropic place. But it is rare for us to see it that way. In *Living with Complexity*, Donald A. Norman offers a perspective on why we need complexity:

We seek rich, satisfying lives, and richness goes along with complexity. Our favorite songs, stories, games, and books are rich, satisfying, and complex. We need complexity even while we crave simplicity... Some complexity is desirable. When things are too simple, they are also viewed as dull and uneventful. Psychologists have demonstrated that people prefer a middle level of complexity: too simple and we are bored, too complex and we are confused. Moreover, the ideal level of complexity is a moving target, because the more expert we become at any subject, the more complexity we prefer. This holds true whether the subject is music or art, detective stories or historical novels, hobbies or movies.

As an example, Norman asks readers to contemplate the complexity we attach to tea and coffee. Most people in most cultures drink tea or coffee each day. Both are simple beverages, made from water and coffee beans or tea leaves. Yet we choose to attach complex rituals to them. Even those of us who would not consider ourselves to be connoisseurs have preferences. Offer to make coffee for a room full of people, and we can be sure that each person will want it made in a different way.

Coffee and tea start off as simple beans or leaves, which must be dried or roasted, ground and infused with water to produce the end result. In principle, it should be easy to make a cup of coffee or tea. Simply let the ground beans or tea leaves [steep] in hot water for a while, then separate the grounds and tea leaves from the brew and drink. But to the coffee or tea connoisseur, the quest for the perfect taste is long-standing. What beans? What tea leaves? What temperature water and for how long? And what is the proper ratio of water to leaves or coffee?

The quest for the perfect coffee or tea maker has been around as long as the drinks themselves. Tea ceremonies are particularly complex, sometimes requiring years of study to master the intricacies. For both tea and coffee, there has been a continuing battle between those who seek convenience and those who seek perfection.

Complexity, in this way, can enhance our enjoyment of a cup of tea or coffee. It's one thing to throw some instant coffee in hot water. It's different to select the perfect beans, grind them ourselves, calculate how much water is required, and use a fancy device. The question of whether this ritual makes the coffee taste better or not is irrelevant. The point is the elaborate surrounding ritual. Once again, we see complexity as superior.

"Simplicity is a great virtue but it requires hard work to achieve it and education to appreciate it. And to make matters worse: complexity sells better."

— Edsger W. Dijkstra
The Problem with Complexity

Imagine a person who sits down one day and plans an elaborate morning routine. Motivated by the routines of famous writers they have read about, they lay out their ideal morning. They decide they will wake up at 5 a.m., meditate for 15 minutes, drink a liter of lemon water while writing in a journal, read 50 pages, and then prepare coffee before planning the rest of their day.

The next day, they launch into this complex routine. They try to keep at it for a while. Maybe they succeed at first, but entropy soon sets in and the routine gets derailed. Sometimes they wake up late and do not have time to read. Their perceived ideal routine has many different moving parts. Their actual behavior ends up being different each day, depending on random factors.

Now imagine that this person is actually a famous writer. A film crew asks to follow them around on a “typical day.” On the day of filming, they get up at 7 a.m., write some ideas, make coffee, cook eggs, read a few news articles, and so on. This is not really a routine; it is just a chaotic morning based on reactive behavior. When the film is posted online, people look at the morning and imagine they are seeing a well-planned routine rather than the randomness of life.

This hypothetical scenario illustrates the issue with complexity: it is unsustainable without effort.

The more individual constituent parts a system has, the greater the chance of its breaking down. Charlie Munger once said that “Where you have complexity, by nature you can have fraud and mistakes.” Any complex system — be it a morning routine, a business, or a military campaign — is difficult to manage. Addressing one of the constituent parts inevitably affects another (see [the Butterfly Effect](#)). Unintended and unexpected consequences are likely to occur.

As Daniel Kahneman and Amos Tversky wrote in 1974 (in [Judgment Under Uncertainty: Heuristics and Biases](#)): “A complex system, such as a nuclear reactor or the human body, will malfunction if any of its essential components fails. Even when the likelihood of failure in each component is slight, the probability of an overall failure can be high if many components are involved.”

This is why complexity is less common than we think. It is unsustainable without constant maintenance, self-organization, or adaptation. Chaos tends to disguise itself as complexity. *“Human beings are pattern-seeking animals. It’s part of our DNA. That’s why conspiracy theories and gods are so popular: we always look for the wider, bigger explanations for things.”*

— Adrian McKinty, *The Cold Cold Ground*
Complexity Bias and Conspiracy Theories

A musician walks barefoot across a zebra-crossing on an album cover. People decide he died in a car crash and was replaced by a lookalike. A politician’s eyes look a bit odd in a blurry photograph. People conclude that he is a blood-sucking reptilian alien taking on a human form. A photograph shows an indistinct shape beneath the water of a Scottish lake. The area floods with tourists hoping to glimpse a surviving prehistoric creature. A new technology overwhelms people. So, they deduce that it is the product of a government mind-control program.

Conspiracy theories are the ultimate symptom of our desire to find complexity in the world. We don’t want to acknowledge that the world is entropic. Disasters happen and chaos is our natural state. The idea that hidden forces animate our lives is an appealing one. It seems rational. But as we know, we are all much less rational and logical than we think. Studies have shown that a high percentage of people believe in some sort of conspiracy. It’s not a fringe concept. According to research by Joseph E. Uscinski and Joseph M. Parent, about one-third of Americans believe the notion that Barack Obama’s birth

certificate is fake. Similar numbers are convinced that 9/11 was an inside job orchestrated by George Bush. Beliefs such as these are present in all types of people, regardless of class, age, gender, race, socioeconomic status, occupation, or education level.

Conspiracy theories are invariably far more complex than reality. Although education does reduce the chances of someone's believing in conspiracy theories, one in five Americans with postgraduate degrees still hold conspiratorial beliefs.

Uscinski and Parent found that, just as uncertainty led Skinner's pigeons to see complexity where only randomness existed, a sense of losing control over the world around us increases the likelihood of our believing in conspiracy theories. Faced with natural disasters and political or economic instability, we are more likely to concoct elaborate explanations. In the face of horrific but chaotic events such as Hurricane Katrina, or the recent Grenfell Tower fire, many people decide that secret institutions are to blame.

Take the example of the "Paul McCartney is dead" conspiracy theory. Since the 1960s, a substantial number of people have believed that McCartney died in a car crash and was replaced by a lookalike, usually said to be a Scottish man named William Campbell. Of course, conspiracy theorists declare, The Beatles wanted their most loyal fans to know this, so they hid clues in songs and on album covers.

The beliefs surrounding the Abbey Road album are particularly illustrative of the desire to spot complexity in randomness and chaos. A police car is parked in the background — an homage to the officers who helped cover up the crash. A car's license plate reads "LMW 28IF" — naturally, a reference to McCartney being 28 if he had lived (although he was 27) and to Linda McCartney (whom he had not met yet). Matters were further complicated once The Beatles heard about the theory and began to intentionally plant "clues" in their music. The song "I'm So Tired" does in fact feature backwards mumbling about McCartney's supposed death. The 1960s were certainly a turbulent time, so is it any wonder that scores of people pored over album art or played records backwards, looking for evidence of a complex hidden conspiracy?

As Henry Louis Gates Jr. wrote, "Conspiracy theories are an irresistible labor-saving device in the face of complexity."

Complexity Bias and Language

We have all, at some point, had a conversation with someone who speaks like philosopher Theodor Adorno wrote: using incessant jargon and technical terms even when simpler synonyms exist and would be perfectly appropriate. We have all heard people say things which we do not understand, but which we do not question for fear of sounding stupid.

Jargon is an example of how complexity bias affects our communication and language usage. When we use jargon, especially out of context, we are putting up unnecessary semantic barriers that reduce the chances of someone's challenging or refuting us.

In an article for *The Guardian*, James Gingell describes his work translating scientific jargon into plain, understandable English:

It's quite simple really. The first step is getting rid of the technical language. Whenever I start work on refining a rough-hewn chunk of raw science into something more pleasant I use David Dobbs' (rather violent) aphorism as a guiding principle: "Hunt down jargon like a mercenary possessed, and kill it." I eviscerate acronyms and euthanise decrepit Latin and Greek. I expunge the esoteric. I trim and clip and pare and hack and burn until only the barest, most easily understood elements remain.

[...]

Jargon...can be useful for people as a shortcut to communicating complex concepts. But it's intrinsically limited: it only works when all parties involved know the code. That may be an obvious point but it's worth emphasising — to communicate an idea to a broad, non-specialist audience, it doesn't matter how good you are at embroidering your prose with evocative imagery and clever analogies, the jargon simply must go."

Gingell writes that even the most intelligent scientists struggle to differentiate between thinking (and speaking and writing) like a scientist, and thinking like a person with minimal scientific knowledge.

Unnecessarily complex language is not just annoying. It's outright harmful. The use of jargon in areas such as politics and economics does real harm. People without the requisite knowledge to understand it feel alienated and removed from important conversations. It leads people to believe that they are not intelligent enough to understand politics, or not educated enough to comprehend economics. When a politician talks of fiscal charters or rolling four-quarter growth measurements in a public statement, they are sending a crystal clear message to large numbers of people whose lives will be shaped by their decisions: this is not about you.

Complexity bias is a serious issue in politics. For those in the public eye, complex language can be a means of minimizing the criticism of their actions. After all, it is hard to dispute something you don't really understand. Gingell considers jargon to be a threat to democracy:

If we can't fully comprehend the decisions that are made for us and about us by the government then how can we possibly revolt or react in an effective way? Yes, we have a responsibility to educate ourselves more on the big issues, but I also think it's important that politicians and journalists meet us halfway.

[...]

Economics and economic decisions are more important than ever now, too. So we should implore our journalists and politicians to write and speak to us plainly. Our democracy depends on it.

In his essay "Politics and the English Language," George Orwell wrote:

In our time, political speech and writing are largely the defence of the indefensible. ... Thus, political language has to consist largely of euphemism, question-begging and sheer cloudy vagueness. Defenceless villages are bombarded from the air, the inhabitants driven out into the countryside, the cattle machine-gunned, the huts set on fire with incendiary bullets: this is called pacification. Millions of peasants are robbed of their farms and sent trudging along the roads with no more than they can carry: this is called transfer of population or rectification of frontiers. People are imprisoned for years without trial, or shot in the back of the neck or sent to die of scurvy in Arctic lumber camps: this is called elimination of unreliable elements.

An example of the problems with jargon is the Sokal affair. In 1996, Alan Sokal (a physics professor) submitted a fabricated scientific paper entitled "Transgressing the Boundaries: Towards a Transformative Hermeneutics of Quantum Gravity." The paper had absolutely no relation to reality and argued that quantum gravity is a social and linguistic construct. Even so, the paper was published in a respected journal. Sokal's paper consisted of convoluted, essentially meaningless claims, such as this paragraph:

Secondly, the postmodern sciences deconstruct and transcend the Cartesian metaphysical distinctions between humankind and Nature, observer and observed, Subject and Object. Already quantum mechanics, earlier in this century, shattered the ingenious Newtonian faith in an objective, pre-linguistic world of material objects "out there"; no longer could we ask, as Heisenberg put it, whether "particles exist in space and time objectively."

(If you're wondering why no one called him out, or more specifically why we have a bias to not call BS out, check out pluralistic ignorance).

Jargon does have its place. In specific contexts, it is absolutely vital. But in everyday communication, its use is a sign that we wish to appear complex and therefore more intelligent. Great thinkers throughout the ages have stressed the crucial importance of using simple language to convey complex ideas. Many of the ancient thinkers whose work we still reference today — people like Plato, Marcus Aurelius, Seneca, and Buddha —

were known for their straightforward communication and their ability to convey great wisdom in a few words.

“Any intelligent fool can make things bigger, more complex, and more violent. It takes a touch of genius — and a lot of courage — to move in the opposite direction.”

— Ernst F. Schumacher

How Can We Overcome Complexity Bias?

The most effective tool we have for overcoming complexity bias is Occam's razor. Also known as the principle of parsimony, this is a problem-solving principle used to eliminate improbable options in a given situation. Occam's razor suggests that the simplest solution or explanation is usually the correct one. When we don't have enough empirical evidence to disprove a hypothesis, we should avoid making unfounded assumptions or adding unnecessary complexity so we can make quick decisions or establish truths.

An important point to note is that Occam's razor does not state that the simplest hypothesis is the correct one, but states rather that it is the best option before the establishment of empirical evidence. It is also useful in situations where empirical data is difficult or impossible to collect. While complexity bias leads us towards intricate explanations and concepts, Occam's razor can help us to trim away assumptions and look for foundational concepts.

Returning to Skinner's pigeons, had they known of Occam's razor, they would have realized that there were two main possibilities:

- Their behavior affects the food delivery.

Or:

- Their behavior is irrelevant because the food delivery is random or on a timed schedule.

Using Occam's razor, the head-bobbing, circles-turning pigeons would have realized that the first hypothesis involves numerous assumptions, including:

- There is a particular behavior they must enact to receive food.
- The delivery mechanism can somehow sense when they enact this behavior.
- The required behavior is different from behaviors that would normally give them access to food.
- The delivery mechanism is consistent.

And so on. Occam's razor would dictate that because the second hypothesis is the simplest, involving the fewest assumptions, it is most likely the correct one.

So many geniuses, are really good at eliminating unnecessary complexity. Einstein, for instance, was a master at sifting the essential from the non-essential. Steve Jobs was the same.

122. Sifting the Essential from the Non-Essential

The most essential skill we've never been taught is learning what to ignore.

The person who can focus their attention on what matters goes further than the person who can't.

When we don't know what to ignore, everything assumes equal importance. Time is wasted on things that don't move us forward.

You can focus your time on the non-essential or the essential, but not both. All the time you spend on the non-essentials comes at the expense of the essentials.

Knowing what to ignore allows you to focus your time on what matters. Of course, this is harder than it seems.

Let me tell you a story about Albert Einstein.

A lot of people think Einstein's greatest ability was his mathematical mind. It wasn't.

Granted it's probably better than yours or mine, but most people in the know consider his mathematical gifts average at best.

How does someone with average mathematical gifts rise to the top?

He had another skill. A skill most people don't even think about.

Einstein's greatest skill was keeping things simple by knowing what mattered and what didn't. When everyone else was lost in complexity, he could keep things simple. He knew what to ignore.

In his short biographical memoir on Einstein, John Wheeler points out that Einstein didn't understand more complicated things than others; he appreciated the value of simplicity more than others.

Many a man in the street thinks of Einstein as a man who could only make headway in his work by dint of pages of complicated mathematics; the truth is the direct opposite. As Hilbert put it, "Every boy in the streets of our mathematical Gottingen understands more about four-dimensional geometry than Einstein. Yet, despite that, Einstein did the work and not the mathematicians." Time and again, in the photoelectric effect, in relativity, in gravitation, the amateur grasped the simple point that had eluded the expert.

While it's tempting to think that Einstein was born with this skill, that would be a lie. He intentionally developed it as an adult.

"I soon learned," Einstein wrote, "to scent out what was able to lead to fundamentals and to turn aside from everything else, from the multitude of things that clutter up the mind."

Where did Einstein acquire this ability to sift the essential from the non-essential?

In the view of many, the position of clerk of the Swiss patent office was no proper job at all, but it was the best job available to anyone with (Einstein's) unpromising university record.

He served in the Bern office for seven years, from June 23, 1902 to July 6, 1909. Every morning he faced his quota of patent applications. Those were the days when a patent application had to be accompanied by a working model. Over and above the applications and the models was the boss, a kind man, a strict man, a wise man. He gave strict instructions: explain very briefly, if possible in a single sentence, why the device will work or why it won't; why the application should be granted or why it should be denied.

Day after day Einstein had to distill the central lesson out of objects of the greatest variety that man has power to invent. Who knows a more marvelous way to acquire a sense of what physics is and how it works? It is no wonder that Einstein always delighted in the machinery of the physical world—from the action of a compass needle to the meandering of a river, and from the perversities of a gyroscope to the drive of Flettner's rotor ship.

Who else but a patent clerk could have discovered the theory of relativity? "Who else,"

Wheeler writes, "could have distilled this simple central point from all the clutter of electromagnetism than someone whose job it was over and over to extract simplicity out of complexity."

We have a passion for keeping things simple.

Charlie Munger

Most of us don't know what to ignore. Because of that, we try to consume more information, thinking it will help us. If you find yourself searching for more information and you're not quite sure what you're looking for, it's a strong indication you don't understand the problem. If you understood the problem, you'd know what information to hone in on. When all information is valued equally, irrelevant information is over-valued, and relevant information is under-valued.

The best in the world have an uncanny ability to focus on the few variables that matter and ignore the rest.

What can I take away from this article?

Most information is irrelevant. Most of our time spent chasing it is wasted. Knowing what to ignore saves us from wasting time, and it helps us spend more time on the things that matter. The more time we spend on what matters, the better the results we get.

Developing the skills of sifting the essential from the non-essential is within our grasp. Try these five things:

1. Focus on understanding basic, timeless, general principles of the world and use them to help filter people, ideas, and projects;
2. Take time to think about what we're doing by writing it out;
3. Keep it simple. There is a natural entropy to life that nudges us towards complexity. Remove everything inessential;
4. Think backwards about what we want to avoid;
5. Think long and hard about the voices and information you let into your mind. Think about who you follow on social media. Think about the books you read. The newsletter you subscribe to.

123. Poker, Speeding Tickets, and Expected Value: Making Decisions in an Uncertain World

You can train your brain to think like CEOs, professional poker players, investors, and others who make tricky decisions in an uncertain world by weighing probabilities.

All decisions involve potential tradeoffs and opportunity costs. The question is, how can we make the best possible choices when the factors involved are often so complicated and confusing? How can we determine which statistics and metrics are worth paying attention to? How do we think about averages?

Expected value is one of the simplest tools you can use to think better. While not a natural way of thinking for most people, it instantly turns the world into shades of grey by forcing us to weigh probabilities and outcomes. Once we've mastered it, our decisions become supercharged. We know which risks to take, when to quit projects, and when to go all in.

"Take the probability of loss times the amount of possible loss from the probability of gain times the amount of possible gain. That is what we're trying to do. It's imperfect but that's what it's all about."

— Warren Buffett

Expected value refers to the long-run average of a random variable.

If you flip a fair coin ten times, the heads-to-tails ratio will probably not be exactly equal. If you flip it one hundred times, the ratio will be closer to 50:50, though again not exactly. But for a huge number of iterations, you can expect heads to come up half the time and tails the other half. The law of large numbers dictates that the values will, in the long term, regress to the mean, even if the first few flips seem unequal.

The more coin flips, the closer you get to the 50:50 ratio. If you bet a sum of money on a coin flip, the potential winnings on a fair coin have to be bigger than your potential loss to make the expected value positive.

We make many expected-value calculations without even realizing it. If we decide to stay up late and have a few drinks on a Tuesday, we regard the expected value of an enjoyable evening as higher than the expected costs the following day. If we decide to always leave early for appointments, we weigh the expected value of being on time against the frequent instances when we arrive early. When we take on work, we view the expected value in terms of income and other career benefits as higher than the cost in terms of time and/or sanity.

Likewise, anyone who reads a lot knows that most books they choose will have minimal impact on them, while a few books will change their lives and be of tremendous value.

Looking at the required time and money as an investment, books have a positive expected value (provided we choose them with care and make use of the lessons they teach).

These decisions might seem obvious. But the math behind them would be somewhat complicated if we tried to sit down and calculate it. Who pulls out a calculator before deciding whether to open a bottle of wine (certainly not me) or walk into a bookstore?

The factors involved are impossible to quantify in a non-subjective manner – like trying to explain how to catch a baseball. We just have a feel for them. This expected-value analysis is unconscious – something to consider if you have ever labeled yourself as “bad at math.”

Parking Tickets

Another example of the expected value is parking tickets. Let's say that a parking spot costs \$5, and the fine for not paying is \$10. If you can expect to be caught one-third of the time, why pay for parking? The expected value of doing so is negative. It's a disincentive. You can park without paying three times and pay only \$10 in fines, instead of paying \$15 for three parking spots. But if the fine is \$100, the probability of getting caught would have to be higher than one in twenty for it to be worthwhile. This is why fines tend to seem

excessive. They cover the people who are not caught while giving an incentive for everyone to pay.

Consider speeding tickets. Here, the expected value can be more abstract, encompassing different factors. If speeding on the way to work saves 15 minutes, then a monthly \$100 fine might seem worthwhile to some people. For most of us, though, a weekly fine would mean that speeding has a negative expected value. Add in other disincentives (such as the loss of your driver's license), and speeding is not worth it. So the calculation is not just financial; it takes into account other tradeoffs as well.

The same goes for free samples and trial periods on subscription services. Many companies (such as Graze, Blue Apron, and Amazon Prime) offer generous free trials. How can they afford to do this? Again, it comes down to expected value. The companies know how much the free trials cost them. They also know the probability of someone paying afterward and the lifetime value of a customer. Basic math reveals why free trials are profitable. Say that a free trial costs the company \$10 per person, and one in ten people then sign up for the paid service, going on to generate \$150 in profits. The expected value is positive. If only one in twenty people sign up, the company needs to find a cheaper free trial or scrap it.

Similarly, expected value applies to services that offer a free "lite" version (such as Buffer and Spotify). Doing so costs them a small amount or even nothing. Yet it increases the chance of someone's deciding to pay for the premium version. For the expected value to be positive, the combined cost of the people who never upgrade needs to be lower than the profit from the people who do pay.

Lottery tickets prove useless when viewed through the lens of expected value. If a ticket costs \$1 and there is a possibility of winning \$500,000, it might seem as if the expected value of the ticket is positive. But it is almost always negative. If one million people purchase a ticket, the expected value is \$0.50. That difference is the profit that lottery companies make. Only on sporadic occasions is the expected value positive, even though the probability of winning remains minuscule.

Failing to understand expected value is a common logical fallacy. Getting a grasp of it can help us to overcome many limitations and cognitive biases.

"Constantly thinking in expected value terms requires discipline and is somewhat unnatural. But the leading thinkers and practitioners from somewhat varied fields have converged on the same formula: focus not on the frequency of correctness, but on the magnitude of correctness."

— Michael Mauboussin

Expected Value and Poker

Let's look at poker. How do professional poker players manage to win large sums of money and hold impressive track records? Well, we can be certain that the answer isn't all luck, although there is some of that involved.

Professional players rely on mathematical mental models that create order among random variables. Although these models are basic, it takes extensive experience to create the *fingerspitzengefühl* ("fingertips feeling," or instinct) necessary to use them.

A player needs to make correct calculations every minute of a game with an automaton-like mindset. Emotions and distractions can corrupt the accuracy of raw math.

In a game of poker, the expected value is the average return on each dollar invested in the pot. Each time a player makes a bet or call, they are taking into account the probability of making more money than they invest. If a player is risking \$100, with a 1 in 5 probability of success, the pot must contain at least \$500 for the bet to be safe. The expected value per call is at least equal to the amount the player stands to lose. If the pot contains \$300 and

the probability is 1 in 5, the expected value is negative. The idea is that even if this tactic is unsuccessful at times, in the long run, the player will profit.

Expected-value analysis gives players a clear idea of probabilistic payoffs. Successful poker players can win millions one week, then make nothing or lose money the next, depending on the probability of winning. Even the best possible hands can lose due to simple probability. With each move, players also need to use Bayesian updating to adapt their calculations, because sticking with a prior figure could prove disastrous. Casinos make their fortunes from people who bet on situations with a negative expected value.

Expected Value and the Ludic Fallacy

In *The Black Swan*, Nassim Taleb explains the difference between everyday randomness and randomness in the context of a game or casino. Taleb coined the term “ludic fallacy” to refer to “the misuse of games to model real-life situations.” (Or, as the website logicallyfallacious.com puts it: the assumption that flawless statistical models apply to situations where they don’t actually apply.)

In Taleb’s words, gambling is “*sterilized* and domesticated uncertainty. In the casino, you know the rules, you can calculate the odds... ‘The casino is the only human venture I know where the probabilities are known, Gaussian (i.e., bell-curve), and almost computable.’ You cannot expect the casino to pay out a million times your bet, or to change the rules abruptly during the game....”

Games like poker have a defined, calculable expected value. That’s because we know the outcomes, the cards, and the math. Most decisions are more complicated. If you decide to bet \$100 that it will rain tomorrow, the expected value of the wager is incalculable. The factors involved are too numerous and complex to compute. Relevant factors do exist; you are more likely to win the bet if you live in England than if you live in the Sahara, for example. But that doesn’t rule out Black Swan events, nor does it give you the neat probabilities which exist in games. In short, there is a key distinction between Knightian risks, which are computable because we have enough information to calculate the odds, and Knightian uncertainty, which is non-computable because we don’t have enough information to calculate odds accurately. (This distinction between risk and uncertainty is based on the writings of economist Frank Knight.) Poker falls into the former category. Real-life is in the latter. If we take the concept literally and only plan for the expected, we will run into some serious problems.

As Taleb writes in *Fooled By Randomness*:

Probability is not a mere computation of odds on the dice or more complicated variants; it is the acceptance of the lack of certainty in our knowledge and the development of methods for dealing with our ignorance. Outside of textbooks and casinos, probability almost never presents itself as a mathematical problem or a brain teaser. Mother nature does not tell you how many holes there are on the roulette table, nor does she deliver problems in a textbook way (in the real world one has to guess the problem more than the solution).

The Monte Carlo Fallacy

Even in the domesticated environment of a casino, probabilistic thinking can go awry if the principle of expected value is forgotten. This famously occurred in Monte Carlo Casino in 1913. A group of gamblers lost millions when the roulette table landed on black 26 times in a row. The probability of this occurring is no more or less likely than the other 67,108,863 possible permutations, but the people present kept thinking, “It has to be red next time.” They saw the likelihood of the wheel landing on red as higher each time it landed on black. In hindsight, what sense does that make? A roulette wheel does not remember the color it landed on last time. The likelihood of either outcome is exactly 50% with each spin, regardless of the previous iteration. So the potential winnings for each spin need to be at least twice the bet a player makes, or the expected value is negative.

“A lot of people start out with a 400-horsepower motor but only get 100 horsepower of output. It’s way better to have a 200-horsepower motor and get it all into output.”

— Warren Buffett

Given all the casinos and roulette tables in the world, the Monte Carlo incident had to happen at some point. Perhaps some day a roulette wheel will land on red 26 times in a row and the incident will repeat. The gamblers involved did not consider the negative expected value of each bet they made. We know this mistake as the Monte Carlo fallacy (or the “gambler’s fallacy” or “the fallacy of the maturity of chances”) – the assumption that prior independent outcomes influence future outcomes that are actually also independent. In other words, people assume that “a random process becomes less random and more predictable as it is repeated”¹.

It’s a common error. People who play the lottery for years without success think that their chance of winning rises with each ticket, but the expected value is unchanged between iterations. Amos Tversky and Daniel Kahneman consider this kind of thinking a component of the representativeness heuristic, stating that the more we believe we control random events, the more likely we are to succumb to the Monte Carlo fallacy.

Magnitude over Frequency

Steven Crist, in his book *Bet with the Best*, offers an example of how an expected-value mindset can be applied. Consider a hypothetical race with four horses. If you’re trying to maximize return on investment, you might want to avoid the horse with a high likelihood of winning. Crist writes,

*The point of this exercise is to illustrate that even a horse with a very high likelihood of winning can be either a very good or a very bad bet, and that the difference between the two is determined by only one thing: the odds.”*²

Everything comes down to payoffs. A horse with a 50% chance of winning might be a good bet, but it depends on the payoff. The same holds for a 100-to-1 longshot. It’s not the frequency of winning but the magnitude of the win that matters.

Error Rates, Averages, and Variability

When Bill Gates walks into a room with 20 people, the average wealth per person in the room quickly goes beyond a billion dollars. It doesn’t matter if the 20 people are wealthy or not; Gates’s wealth is off the charts and distorts the results.

An old joke tells of the man who drowns in a river which is, on average, three feet deep. If you’re deciding to cross a river and can’t swim, the range of depths matters a heck of a lot more than the average depth.

The Use of Expected Value: How to Make Decisions in an Uncertain World

Thinking in terms of expected value requires discipline and practice. And yet, the top performers in almost any field think in terms of probabilities. While this isn’t natural for most of us, once you implement the discipline of the process, you’ll see the quality of your thinking and decisions improve.

In poker, players can predict the likelihood of a particular outcome. In the vast majority of cases, we cannot predict the future with anything approaching accuracy. So what use is the expected value outside gambling? It turns out, quite a lot. Recognizing how expected value works puts any of us at an advantage. We can mentally leap through various scenarios and understand how they affect outcomes.

Expected value takes into account wild deviations. Averages are useful, but they have limits, as the man who tried to cross the river discovered. When making predictions about the future, we need to consider the range of outcomes. The greater the possible variance from the average, the more our decisions should account for a wider range of outcomes.

There’s a saying in the design world: when you design for the average, you design for no one. Large deviations can mean more risk—which is not always a bad thing. So expected-

value calculations take into account the deviations. If we can make decisions with a positive expected value and the lowest possible risk, we are open to large benefits. Investors use expected value to make decisions. Choices with a positive expected value and minimal risk of losing money are wise. Even if some losses occur, the net gain should be positive over time. In investing, unlike in poker, the potential losses and gains cannot be calculated in exact terms. Expected-value analysis reveals opportunities that people who just use probabilistic thinking often miss. A trade with a low probability of success can still carry a high expected value. That's why it is crucial to have a large number of robust mental models. As useful as probabilistic thinking can be, it has far more utility when combined with expected value.

Understanding expected value is also an effective way to overcome the sunk costs fallacy. Many of our decisions are based on non-recoverable past investments of time, money, or resources. These investments are irrelevant; we can't recover them, so we shouldn't factor them into new decisions. Sunk costs push us toward situations with a negative expected value. For example, consider a company that has invested considerable time and money in the development of a new product. As the launch date nears, they receive irrefutable evidence that the product will be a failure. Perhaps research shows that customers are disinterested, or a competitor launches a similar, better product. The sunk costs fallacy would lead them to release their product anyway. Even if they take a loss. Even if it damages their reputation. After all, why waste the money they spent developing the product? Here's why: Because the product has a negative expected value, which will only worsen their losses. An escalation of commitment will only increase sunk costs.

When we try to justify a prior expense, calculating the expected value can prevent us from worsening the situation. The sunk costs fallacy robs us of our most precious resource: time. Each day we are faced with the choice between continuing and quitting numerous endeavors. Expected-value analysis reveals where we should continue, and where we should cut our losses and move on to a better use of time and resources. It's an efficient way to work smarter, and not engage in unnecessary projects.

Thinking in terms of expected value will make you feel awkward when you first try it. That's the hardest thing about it; you need to practice it a while before it becomes second nature. Once you get the hang of it, you'll see that it's valuable in almost every decision. That's why the most rational people in the world constantly think about expected value. They've uncovered the key insight that the magnitude of correctness matters more than its frequency. And yet, human nature is such that we're happier when we're frequently right.

124. Making the Most of Second Chances

We all get lucky. Once in a while we do something really stupid that could have resulted in death, but didn't. Just the other day, I saw someone who was texting walk out into oncoming traffic, narrowly avoiding the car whose driver slammed on the brakes. As the adrenaline starts to dissipate, we realize that we don't ever want to be in that situation again. What can we do? We can make the most of our second chances by building margins of safety into our lives.

What is a margin of safety and where can I get one?

The concept is a cornerstone of engineering. Engineers design systems to withstand significantly more emergencies, unexpected loads, misuse, or degradation than would normally be expected.

Take a bridge. You are designing a bridge to cross just under two hundred feet of river. The bridge has two lanes going in each direction. Given the average car size, the bridge could reasonably carry 50 to 60 cars at a time. At 4,000 pounds per car, your bridge needs to be able to carry at least 240,000 pounds of weight; otherwise, don't bother building it. So that's the minimum consideration for safety — but only the worst engineer would stop there.

Can anyone walk across your bridge? Can anyone park their car on the shoulder? What if cars get heavier? What if 20 cement trucks are on the bridge at the same time? How does the climate affect the integrity of your materials over time? You don't want the weight capacity of the bridge to ever come close to the actual load. Otherwise, one seagull decides to land on the railing and the whole structure collapses.

Considering these questions and looking at the possibilities is how you get the right information so you can adjust your specs to build in a margin of safety. That's the difference between what your system is expected to withstand and what it actually could. So when you are designing a bridge, the first step is to figure out the maximum load it should ever see (bumper-to-bumper vehicles, hordes of tourist groups, and birds perched wing to wing), and then you design for at least double that load.

Knowing that the infrastructure was designed to withstand significantly more than the anticipated maximum load makes us happy when we are on bridges, or in airplanes, or jumping on the bed in our second-story bedroom. We feel confident that many smart people have conspired to make these activities as safe as possible. We're so sure of this

that it almost never crosses our minds. Sure, occasional accidents happen. But it is remarkably reassuring that these structures can withstand quite a bit of the unexpected. So how do we make ourselves a little more resilient? Less susceptible to the vagaries of change? Turns out that engineers aren't the only ones obsessed with building in margins of safety. Spies are pretty good at it, too, and we can learn a lot from them.

Operation Kronstadt, by Harry Ferguson, chronicles the remarkable story of Paul Dukes, the only British secret agent working in Russia in 1919, and the equally amazing adventures of the small team that was sent in to rescue him.

Paul Dukes was not an experienced spy. He was actually a pianist. It was his deep love of Russian culture that led to him to approach his government and volunteer for the mission of collecting information on Bolshevik activities in St. Petersburg. As Ferguson writes, "Paul had no military experience, let alone any experience of intelligence work and yet they were going to send him back into one of the toughest espionage environments in the world."

However, MI6, the part of British Intelligence that Paul worked for, wasn't exactly the powerful and well-prepared agency that it's portrayed as today. Consider this description by Ferguson: "having dragged Paul out of Russia, MI6 did not appear to have given much thought to how he should get back or how he would survive once he got there: 'As to the means whereby you gain access to the country, under what cover you will live there, and how you will send out reports, we shall leave it to you, being best informed as to the conditions'."

So off went Paul into Russia, not as a musician but as a spy. No training, no gadgets, no emergency network, no safe houses. Just a bunch of money and sentiments of 'good luck'. So it is all the more amazing that Paul Dukes turned out to be an excellent spy. After reading his story, I think the primary reason for this is that he learned extremely quickly from his experiences. One of the things he learned quickly was how to build margins of safety into his tradecraft.

There is no doubt that the prospect of death wakes us up. We don't often think about how dangerous something can be until we almost die doing it. Then, thanks to our big brains that let us learn from experience, we adapt. We recognize that if we don't, we might not be so lucky next time. And no one wants to rely on luck as a survival strategy.

This is where margins of safety come in. We build them to reduce the precariousness of chance.

Imagine you are in St. Petersburg in 1919. What you have going for you is that you speak the language, understand the culture, and know the streets. Your major problem is that you have no idea how to start this spying thing. How do you get contacts and build a network in a city that is under psychological siege? The few names you have been given come from dubious sources at the border, and the people attached to those names may have been compromised, arrested, or both. You have nowhere to sleep at night, and although you have some money, it can't buy anything, not even food, because there is nothing for sale. The whole country is on rations.

Not to mention, if by some miracle you actually get a few good contacts who give you useful information, how do you get it home? There are no cell phones or satellites. Your passport is fake and won't hold up to any intense scrutiny, yet all your intelligence has to be taken out by hand from a country that has sealed its borders. And it's 1919. You can't hop on a plane or drive a car. Train or foot are your only options.

This is what Paul Dukes faced. Daunting to be sure. Which is why his ultimate success reads like the improbable plot of a Hollywood movie. Although he made mistakes, he learned from them as they were happening.

Consider this tense moment as described by Ferguson:

The doorbell in the flat rang loudly and Paul awoke with a start.

He had slept late. Stepanova had kindly allowed him sleep in one of the spare beds and she had even found him an old pair of Ivan's pyjamas. There were no sheets, but there were plenty of blankets and Paul had been cosy and warm. Now it was 7.45 a.m., and here he was half-asleep and without his clothes. Suppose it was the Cheka [Russian Bolshevik Police] at the door? In a panic he realised that he had no idea what to do. The windows of the apartment were too high for him to jump from and like a fool he had chosen a hiding place with no other exits. ... He was reduced to waiting nervously as he stood in Ivan's pyjamas whilst Stepanova shuffled to the door to find out who it was. As he stood there with his stomach in knots, Paul swore that he would never again sleep in a place from which there was only one exit.

One exit was good enough for normal, anticipated use. But one exit wouldn't allow him to adapt to the unexpected, the unusual load produced by the appearance of the state police. So from then on, his sleeping accommodations were chosen with a minimum margin of safety of two exits.

This type of thinking dictated a lot of his actions. He never stayed at the same house more than two nights in a row, and often moved after just one night. He arranged for the occupants to signal him, such as by placing a plant in the window, if they believed the house was unsafe. He siloed knowledge as much as he could, never letting the occupants of one safe house know about the others. Furthermore, as Ferguson writes:

He also arranged a back-up plan in case the Cheka finally got him. He had to pick one trustworthy agent ... and soon Paul began entrusting her with all the details of his movements and told her at which safe house he would be sleeping so that if he did disappear MI6 would have a better idea of who had betrayed him. He even used her as part of his courier service and she hid all his reports in the float while he was waiting for someone who could take them out of the country.

Admittedly this plan didn't provide a large margin of safety, but at least he wasn't so arrogant as to assume he was never going to get captured.

Large margins of safety are not always possible. Sometimes they are too expensive. Sometimes they are not available. Dukes liked to have an extra identity handy should some of his dubious contacts turn him in, but this wasn't always an option in a country that changed identity papers frequently. Most important, though, he was aware that planning for the unexpected was his best chance of staying alive, even if he couldn't always put in place as large a margin of safety as he would have liked. And survival was a daily challenge, not something to take for granted.

The disaster at the Fukushima nuclear power plant taught us a lot about being cavalier regarding margins of safety. The unexpected is just that: not anticipated. That doesn't mean it is impossible or even improbable. The unexpected is not the worst thing that has happened before. It is the worst thing, given realistic parameters such as the laws of physics, that could happen.

In the Fukushima case, the margin of safety was good enough to deal with the weather of the recent past. But preparing for the worst we have seen is not the same as preparing for the worst.

The Fukushima power plant was overwhelmed by a tsunami, creating a nuclear disaster on par with Chernobyl. Given the seismic activity in the area, although a tsunami wasn't predictable, it was certainly possible. The plant could have been designed with a margin of safety to better withstand a tsunami. It wasn't. Why? Because redundancy is expensive. That's the trade-off. You are safer, but it costs more money.

Sometimes when the stakes are low, we decide the trade-off isn't worth it. For instance, maybe we wouldn't pay to insure a wedding ring that wasn't expensive. You would think, however, that power plants wouldn't cut it close. The consequences of a lost ring are some emotional pain and the cost of a new one. The consequences of a nuclear accident are

exponentially higher. Lives are lost, and the environment corrupted. In the Fukushima case, the world will be dealing with the negative effects for a long time.

What decisions would you make differently if you were factoring safety margins into your life? To be fair, you can't put them everywhere. Otherwise, your life might be all margin and no living. But you can identify the maximum load your life is currently designed to withstand and figure out how close to it you are coming.

For example, having your expenses equal 100 percent of your income is allowing you no flexibility in the load you have to carry. A job loss, a bad flood in your neighborhood, or significant sickness are all unexpected events that would change the load your financial structure has to support. Without a margin of safety, such as a healthy savings or investment account, you could find your structure collapsing, compromising the roof over your head.

The idea is to identify the unlikely but possible risks to your survival and build margins of safety that will allow you to continue your lifestyle should these things come to pass. That way, a missed paycheck will be easily absorbed instead of jeopardizing your ability to put food on the table.

To figure out where else you should build margins of safety into your life, think of the times you've been terrified and desperate. Those might be good places to start learning from experience and making the most of your second chances.

125. Bayes and Deadweight: Using Statistics to Eject the Deadweight From Your Life

"[K]nowledge is indeed highly subjective, but we can quantify it with a bet. The amount we wager shows how much we believe in something."

— Sharon Bertsch McGrayne

The quality of your life will, to a large extent, be decided by whom you elect to spend your time with. Supportive, caring, and funny are great attributes in friends and lovers.

Unceasingly negative cynics who chip away at your self-esteem? We need to jettison those people as far and fast as we can.

The problem is, how do we identify these people who add nothing positive — or not enough positive — to our lives?

Few of us keep relationships with obvious assholes. There are always a few painfully terrible family members we have to put up with at weddings and funerals, but normally we choose whom we spend time with. And we've chosen these people because, at some point, our interactions with them felt good.

How, then, do we identify the deadweight? The people who are really dragging us down and who have a high probability of continuing to do so in the future? We can apply the general thinking tool called Bayesian Updating.

Bayes's theorem can involve some complicated mathematics, but at its core lies a very simple premise. Probability estimates should start with what we already know about the world and then be incrementally updated as new information becomes available. Bayes can even help us when that information is relevant but subjective.

How? As McGrayne explains in the quote above, from *The Theory That Would Not Die*, you simply ask yourself to wager on the outcome.

Let's take an easy example.

You are going on a blind date. You've been told all sorts of good things in advance — the person is attractive and funny and has a good job — so of course, you are excited. The date starts off great, living up to expectations. Halfway through you find out they have a cat. You hate cats. Given how well everything else is going, how much should this information affect your decision to keep dating?

Quantify your belief in the most probable outcome with a bet. How much would you wager that harmony on the pet issue is an accurate predictor of relationship success? Ten cents? Ten thousand dollars? Do the thought experiment. Imagine walking into a casino and placing a bet on the likelihood that this person's having a cat will ultimately destroy the relationship. How much money would you take out of your savings and lay on the table? Your answer will give you an idea of how much to factor the cat into your decision-making process. If you wouldn't part with a dime, then I wouldn't worry about it.

This kind of approach can help us when it comes to evaluating our interpersonal relationships. Deciding if someone is a good friend, partner, or co-worker is full of subjective judgments. There is usually some contradictory information, and ultimately no one is perfect. So how do you decide who is worth keeping around?

Let's start with friends. The longer a friendship lasts, the more likely it is to have ups and downs. The trick is to start quantifying these. A hit from a change in geographical proximity is radically different from a hit from betrayal — we need to factor these differences into our friendship formula.

This may seem obvious, but the truth is that we often give the same weight to a wide variety of behaviors. We'll say things like "yeah, she talked about my health problems when I asked her not to, but she always remembers my birthday." By treating all aspects of the friendship equally, we have a hard time making reasonable estimates about the future value of that friendship. And that's how we end up with deadweight.

For the friend who has betrayed your confidence, what you really want to know is the likelihood that she's going to do it again. Instead of trying to remember and analyze every interaction you've ever had, just imagine yourself betting on it. Go back to that casino and head to the friendship roulette wheel. Where would you put your money? All in on "She can't keep her mouth shut" or a few chips on "Not likely to happen again"?

Using a rough Bayesian model in our heads, we're forcing ourselves to quantify what "good" is and what "bad" is. How good? How bad? How likely? How unlikely? Until we do some (rough) guessing at these things, we're making decisions much more poorly than we need to be.

The great thing about using Bayes's theorem is that it encourages constant updating. It also encourages an open mind by giving us the chance to look at a situation from multiple angles. Maybe she really is sorry about the betrayal. Maybe she thought she was acting in your best interests. There are many possible explanations for her behavior and you can use Bayes's theorem to integrate all of her later actions into your bet. If you find yourself reducing the amount of money you'd bet on further betrayal, you can accurately assume that the probability she will betray your trust again has gone down.

Using this strategy can also stop the endless rounds of asking why. Why did that co-worker steal my idea? Who else do I have to watch out for? This what-if thinking is paralyzing. You end up self-justifying your behavior by anticipating the worst possible scenarios you can imagine. Thus, you don't change anything, and you step further away from a solution.

In reality, who cares? The why isn't important; the most relevant task for you is to figure out the probability that your coworker will do it again. Don't spend hours analyzing what to do, get upset over the doomsday scenarios you have come up with, or let a few glasses of wine soften the experience.

Head to your mental casino and place the bet, quantifying all the subjective information in your head that is messy and hard to articulate. You will cut through the endless "but maybes" and have a clear path forward that addresses the probable future. It may make sense to give him the benefit of the doubt. It may also be reasonable to avoid him as much as possible. When you figure out how much you would wager on the potential outcomes, you'll know what to do.

Sometimes we can't just get rid of people who aren't good for us — family being the prime example. But you can also use Bayes to test how your actions will change the probability of outcomes to find ways of keeping the negativity minimal. Let's say you have a cousin who always plans to visit but then cancels. You can't stop being his cousin and saying "you aren't welcome at my house" will cause a big family drama. So what else can you do? Your initial equation — your probability estimate — indicates that the behavior is likely to continue. In your casino, you would comfortably bet your life savings that it will happen again. Now imagine ways in which you could change your behavior. Which of these would reduce your bet? You could have an honest conversation with him, telling him how his actions make you feel. To know if he's able to openly receive this, consider whether your bet would change. Or would you wager significantly less after employing the strategy of always being busy when he calls to set up future visits? And you can dig even deeper. Which of your behaviors would increase the probability that he actually comes? Which behaviors would increase the probability that he doesn't bother making plans in the first place? Depending on how much you like him, you can steer your changes to the outcome you'd prefer. Quantifying the subjective and using Bayes's theorem can help us clear out some of the relationship negativity in our lives.

126. Pyrrhic Victory: Winning the Battle, Losing the War

“War ends at the moment when peace permanently wins out. Not when the articles of surrender are signed or the last shot is fired, but when the last shout of a sidewalk battle fades, when the next generation starts to wonder whether the whole thing ever really happened.”

— Lee Sandlin

The Basics

In a classic American folktale, a stubborn railroad worker decides to prove his skill by competing with a drilling machine. John Henry, enraged to hear that machines might take his job, claims that his digging abilities are superior. A contest is arranged. He goes head to head with the new drill. The result is impressive — the drill breaks after three meters, whereas John Henry makes it to four meters in the same amount of time. As the other workers begin to celebrate his victory, he collapses and dies of exhaustion.

John Henry might have been victorious against the drill, but that small win was meaningless in the face of his subsequent death. In short, we can say that he won the battle but lost the war.

Winning a battle but losing the war is a military mental model that refers to achieving a minor victory that ultimately results in a larger defeat, rendering the victory empty or hollow. It can also refer to gaining a small tactical advantage that corresponds to a wider disadvantage.

One particular type of hollow victory is the Pyrrhic victory, which Wikipedia defines as a victory that “inflicts such a devastating toll on the victor that it is tantamount to defeat.”

That devastating toll can come in the form of an enormous number of casualties, the wasting of resources, high financial costs, damage to land, and other losses. Or, in that folktale, the death of the railroad worker.

Another hollow victory occurs when you engage in a conventional war and prompt a response from an opponent who has significantly more firepower than you do. The attack on Pearl Harbor was considered a victory for the Japanese. However, by provoking an army with superior forces, they set something in motion they could not control.

While the concept of a hollow victory arises in military contexts, understanding the broader principle allows you to apply it to other areas of life. It can often be helpful in the context of non-zero-sum situations, in which both parties suffer even if one has technically succeeded.

[quote]We have won a battle but lost a war whenever we achieve some minor aim that leads to wider loss.[/quote]

We have won a battle but lost a war whenever we achieve some minor (or even major) aim that leads to wider loss. We might win an argument with a partner over a small infraction, only to come across as hostile and damage the relationship. We may achieve a short-term professional goal by working overtime, only to harm our health and reduce our long-term productivity. We might pursue a particular career for the sake of money, but feel unfulfilled and miserable in the process.

“Grand strategy is the art of looking beyond the present battle and calculating ahead. It requires that you focus on your ultimate goal and plot to reach it.”

— Robert Greene, *The 33 Strategies of War*

The Original Pyrrhic Victory

The term “Pyrrhic victory” is named after the Greek king Pyrrhus of Epirus. Between 280 and 279 BC, Pyrrhus’s army managed to defeat the Romans in two major battles. Striding into Italy with 25,000 men and 20 elephants — a new sight for the Romans — Pyrrhus was confident that he could extend his empire. However, the number of lives lost in the process

made the victory meaningless. According to Plutarch, Pyrrhus is said to have told a friend that another victory against the Romans would “utterly undo him.”

Pyrrhus did not have access to anywhere near enough potential recruits to replenish his army. He had, after all, lost most of his men, including the majority of his friends and commanders. Meanwhile, the Romans were only temporarily defeated. They could replace their lost soldiers with relative ease. Even worse, the two losses had enraged the Romans and made them *more* willing to continue fighting. The chastened king gathered his remaining troops and sailed back to Greece.

The Battle of Bunker Hill

A classic example of a Pyrrhic victory is the Battle of Bunker Hill, fought on June 17th, 1775, during the American Revolutionary War. Colonial and British troops grappled for control of the strategically advantageous Bunker Hill in Massachusetts.

Four days earlier, on June 13th, the colonial army received intelligence that the British were planning to take control of the hills around Boston, which would give them greater authority over the nearby harbor. About 1200 colonial soldiers situated themselves on the hills, while others spread throughout the surrounding area. The British army, realizing this, mounted an attack.

The British army succeeded in their aim after the colonial army ran out of ammunition. Yet the Battle of Bunker Hill was anything but a true victory, because the British lost a substantial number of men, including 100 of their officers. This left the British army depleted (having sustained 1000 casualties), low on resources, and without proper management.

This Pyrrhic victory was unexpected; the British troops had far more experience and outnumbered the colonial army by almost 2:1. The Battle of Bunker Hill sapped British morale but was somewhat motivating for the colonials, who had sustained less than half the number of casualties.

In *The American Revolutionary War and the War of 1812*, the situation is described this way:

... the British were stopped by heavy fire from the colonial troops barricaded behind rail fences that had been stuffed with grass, hay, and brush. On the second or third advance, however, the attackers carried the redoubt and forced the surviving defenders, mostly exhausted and weaponless, to flee. ...

If the British had followed this victory with an attack on Dorchester Heights to the South of Boston, it might have been worth the heavy cost. But, presumably, because of their severe losses and the fighting spirit displayed by the rebels, the British commanders abandoned or indefinitely postponed such a plan. Consequently, after Gen. George Washington took colonial command two weeks later, enough heavy guns and ammunition had been collected that he was able in March 1776 to seize and fortify Dorchester Heights and compel the British to evacuate Boston.... Also, the heavy losses inflicted on the British in the Battle of Bunker Hill bolstered the Americans' confidence and showed that the relatively inexperienced colonists could indeed fight on par with the mighty redcoats of the British army.

In *The War of the American Revolution*, Robert W. Coakley writes of the impact of Bunker Hill:

Bunker Hill was a Pyrrhic victory, its strategic effect practically nil since the two armies remained in virtually the same position they had held before. Its consequences, nevertheless, cannot be ignored. A force of farmers and townsmen, fresh from their fields and shops, with hardly a semblance of orthodox military organization, had met and fought on equal terms with a professional British army. ...[N]ever again would British commanders lightly attempt such an assault on Americans in fortified positions.

“I wish we could sell them another hill at the same price.”

— Nathanael Greene, leader of the colonial army

The Battle of Borodino

Fought on September 7, 1812, the Battle of Borodino was the bloodiest day of the Napoleonic Wars. The French army (led by Napoleon) sought to invade Russia. Roughly a quarter of a million soldiers fought at the Battle of Borodino, with more than 70,000 casualties. Although the French army succeeded in forcing the Russians into retreat, their victory was scarcely a triumphant one. Both sides ended up depleted and low on morale without having achieved their respective aims.

The Battle of Borodino is considered a Pyrrhic victory because the French army destroyed itself in the process of capturing Moscow. The Russians had no desire to surrender, and the conflict was more costly for the French than for their opponent.

By the time Napoleon's men began their weary journey back to France, they had little reason to consider themselves victorious. The Battle of Borodino had no clear purpose, as no tactical advantage was gained. Infighting broke out and Napoleon eventually lost both the war and his role as leader of France.

History has shown again and again that attempting to take over Russia is rarely a good idea. Napoleon was at a serious disadvantage to begin with. The country's size and climate made tactical movements difficult. Bringing supplies in proved nearly impossible, and the French soldiers easily succumbed to cold, starvation, and infectious diseases. Even as they hastened to retreat, the Russian army recovered its lost men quickly and continued to whittle away at the remaining French soldiers. Of the original 95,000 French troops, a mere 23,000 returned from Russia (exact figures are impossible to ascertain due to each side's exaggerating or downplaying the losses). The Russian approach to defeating the French is best described as attrition warfare – a stubborn, unending wearing down. Napoleon might have won the Battle of Borodino, but in the process he lost everything he had built during his time as a leader and his army was crushed.

[quote]Pyrrhic victories often serve as propaganda in the long term – for the losing side, not the victors.[/quote]

Something we can note from both Borodino and Bunker Hill is that Pyrrhic victories often serve as propaganda in the long term – for the losing side, not for the victors. As the adage goes, history is written by winners. A Latin saying, *ad victorem spolia* – to the victor belong the spoils – exemplifies this idea. Except that it doesn't quite ring true when it comes to Pyrrhic victories, which tend to be a source of shame for the winning side. In the case of Borodino, it became an emblem of patriotism and pride for the Russians.

"[I]t is much better to lose a battle and win the war than to win a battle and lose the war. Resolve to keep your eyes on the big ball."

— David J. Schwartz, *The Magic of Thinking Big*

Hollow Victories in Business

A company has won a Pyrrhic victory when it leverages all available resources to take over another company, only to be ruined by the financial costs and the loss of key employees. Businesses can also ruin themselves over lawsuits that drain resources, distract managers, and get negative attention in the press.

American Apparel is one instance of a company ending up bankrupt, partially as a result of mounting legal fees. The exact causes of the company's downfall are not altogether understood, though a number of lawsuits are believed to have been a major factor. It began with a series of sexual harassment lawsuits against founder Dov Charney.

American Apparel's board of directors fired Charney after the growing fees associated with defending him began harming the company's finances (as well as its reputation). Charney responded by attempting a hostile takeover, as unwilling to surrender control of the company he founded as Czar Alexander was to surrender Moscow to Napoleon. More

lawsuits followed as American Apparel shareholders and board members seemingly sued everyone in sight and were sued by suppliers, by more than 200 former employees, and by patent holders.

As everyone involved focused on winning their respective battles, the company ended up filing for bankruptcy and losing the war. In short, everyone suffered substantial losses, from Charney himself to the many factory workers who were made redundant.

Hollow Victories in Court Cases

Hollow victories are common in the legal system. For example, consider the following scenarios:

- A divorced couple engages in a lengthy, tedious legal battle over the custody of their children. Eventually, they are given shared custody. Yet the tense confrontations associated with the court case have alienated the children from their parents and removed tens of thousands of dollars from the collective purse.
- A man unknowingly puts up trees that slightly cross over into his neighbor's property. The man tries to come to a compromise by perhaps trimming the trees or allowing the neighbor to cross into his property in exchange for leaving the trees up. No dice; the neighbor sticks to his guns. Unable to resolve the matter, the neighbor sues the man and wins, forcing him to cut down the trees and pay all legal expenses. While the neighbor has technically won the case, he now has an enemy next door, and enemies up and down the street who think he's a Scrooge.
- A freelance illustrator discovers that her work has been used without permission or payment by a non-profit group that printed her designs on T-shirts and sold them, with the proceeds going to charity. The illustrator sues them and wins for copyright infringement, but costs herself and the charity substantial legal fees. Unhappy that the illustrator sued a charity instead of making a compromise, the public boycotts her and she has trouble selling her future work.
- A well-known business magnate discovers that his children are suing him for the release of trust fund money they believe they are owed. He counter-sues, arguing publicly that his children are greedy and don't deserve the money. He wins the case on a legal technicality, but both his public image and his relationships with his children are tarnished. He's kept his money, but not his happiness.

A notable instance of a legal Pyrrhic victory was the decade-long McLibel case, the longest running case in English history. The fast-food chain McDonald's attempted to sue two environmental activists, Helen Steel and David Morris, over leaflets they distributed. McDonald's claimed the contents of the leaflets were false. Steel and Morris claimed they were true.

Court hearings found that both parties were both wrong – some of the claims were verifiable; others were fabricated. After ten years of tedious litigation and negative media attention, McDonald's won the case, but it was far from worthwhile. The (uncollected) £40,000 settlement they were awarded was paltry compared to the millions the legal battle had cost the company. Meanwhile, Steel and Morris chose to represent themselves and spent only £30,000 (both had limited income and did not receive Legal Aid).

Although McDonald's did win the case, it came with enormous costs, both financially and in reputation. The case attracted a great deal of media attention as a result of its David-vs.-Goliath nature. The idea of two unemployed activists taking on an international corporation had an undeniable appeal, and the portrayals of McDonald's were unanimously negative. The case did far more harm to their reputation than a few leaflets distributed in London would have. At one point, McDonald's attempted to placate Steel and Morris by offering to donate money to a charity of their choice, provided that they stopped

criticizing the company publicly and did so only “in private with friends.” The pair responded that they would accept the terms if McDonald’s halted any form of advertising and staff recommended it only “in private with friends.”

“Do not be ashamed to make a temporary withdrawal from the field if you see that your enemy is stronger than you; it is not winning or losing a single battle that matters, but how the war ends.”

— Paulo Coelho, Warrior of the Light

Hollow Victories in Politics

Theresa May’s General Election win is a perfect example of a political Pyrrhic victory, as is the Brexit vote the year prior.

Much like Napoleon at Borodino, David Cameron achieved his aims, only to lose his role as a leader in the process. And much like the French soldiers who defeated the Russians at Borodino, only to find themselves limping home through snow and ice, the triumphant Leave voters now face a drop in wages and general quality of life, making the fulfilment of their desire to leave the European Union seem somewhat hollow. Elderly British people (the majority of whom voted to leave) must deal with dropping pensions and potentially worse healthcare due to reduced funding. Voters won the battle but at a cost that is unknown.

Even before the shock of the Brexit vote had worn off, Britain saw a second dramatic Pyrrhic victory: Theresa May’s train-wreck General Election. Amid soaring inflation, May aimed to win a clear majority and secure her leadership. Although she was not voted out of office, her failure to receive unanimous support only served to weaken her position.

Continued economic decline has weakened it further.

“Victorious warriors win first and then go to war, while defeated warriors go to war first and then seek to win.”

— Sun Tzu, The Art of War

How We Can Avoid Hollow Victories in Our Lives

One important lesson we can learn from hollow victories is the value of focusing on the bigger picture, rather than chasing smaller goals.

One way to avoid winning a battle but losing the war is to think in terms of opportunity costs. Charlie Munger has said that “All intelligent people use opportunity cost to make decisions”; maybe what he should have said is that “All intelligent people should use opportunity cost to make decisions.”

Consider a businessman, well versed in opportunity cost economics, who chooses to work late every night instead of spending time with his family, whom he then alienates and eventually becomes distanced from. The opportunity cost of the time spent at the office between 7-10 pm wasn’t just TV, or dinner, or any other thing he would have done were he at home. It was a good long-term relationship with his wife and children! Talk about opportunity costs! Putting in the late hours may have helped him with the “battle” of business, but what about the “war” of life? Unfortunately, many people realize too late that they paid too high a price for their achievements or victories.

Hollow victories can occur as a result of a person or party focusing on a single goal – winning a lawsuit, capturing a hill, winning an election – while ignoring the wider implications. It’s like looking at the universe by peering into one small corner of space with a telescope.

As was noted earlier, this mental model isn’t relevant just in military, legal, or political contexts; hollow victories can occur in every part of our lives, including relationships, health, personal development, and careers. Understanding military tactics and concepts

can teach us a great deal about being effective leaders, achieving our goals, maintaining relationships, and more.

It's obvious that we should avoid Pyrrhic victories wherever possible, but how do we do that? In spite of situations differing vastly, there are some points to keep in mind:

- Zoom out to see the big picture. By stepping back when we get too focused on minutiae, we can pay more attention to the war, not just the battle. Imagine that you are at the gym when you feel a sharp pain in your leg. You ignore it and finish the workout, despite the pain increasing with each rep. Upon visiting a doctor, you find you have a serious injury and will be unable to exercise until it heals. If you had focused on the bigger picture, you would have stopped the workout, preventing a minor injury from getting worse, and been able to get back to your workouts sooner.
- Keep in mind core principles and focus on overarching goals. When Napoleon sacrificed thousands of his men in a bid to take control of Moscow, he forgot his core role as the leader of the French people. His own country should have been the priority, but he chose to chase more power and ended up losing everything. When we risk something vital – our health, happiness, or relationships – we run the risk of a Pyrrhic victory.
- Recognize that we don't have to lose our minds just because everyone else has. As Warren Buffett once said, "be fearful when others are greedy and greedy when others are fearful." Or, as Nathan Rothschild wrote, "great fortunes are made when cannonballs fall in the harbor, not when violins play in the ballroom." When others are thrashing to win a battle, we would do well to pay attention to the war. What can we notice that they ignore? If we can't (or don't want to) resolve the turmoil, how can we benefit from it?
- Recognize when to give up. We cannot win every battle we engage in, but we can sometimes win the war. In some situations, the optimum choice is to withdraw or surrender to avoid irreparable problems. The goal is not the quick boost from a short-term victory; it is the valuable satisfaction of long-term success.
- Remember that underdogs can win – or at least put up a good fight. Remember what the British learned the hard way at Bunker Hill, and what it cost McDonald's to win the McLibel case. Even if we think we can succeed against a seemingly weaker party, that victory can come at a very high cost.

127. The Law of Unintended Consequences: Shakespeare, Cobra Breeding, and a Tower in Pisa

When we try to make a single change within a complex system, we often end up causing unintended consequences. These can be positive or negative. If we don't anticipate unintended consequences, we can't expect to achieve our desired outcomes.

In 1890, a New Yorker named Eugene Schieffelin took his intense love of Shakespeare's Henry VI to the next level.

Most Shakespeare fanatics channel their interest by going to see performances of the plays, meticulously analyzing them, or reading everything they can about the playwright's life. Schieffelin wanted more; he wanted to look out his window and see the same kind of birds in the sky that Shakespeare had seen.

Inspired by a mention of starlings in Henry VI, Schieffelin released 100 of the non-native birds in Central Park over two years. (He wasn't acting alone – he had the support of scientists and the American Acclimatization Society.) We can imagine him watching the starlings flutter off into the park and hoping for them to survive and maybe breed. Which they did. In fact, the birds didn't just survive; they thrived and bred like weeds.

Unfortunately, Schieffelin's plan worked too well. Far, far too well. The starlings multiplied exponentially, spreading across America at an astonishing rate. Today, we don't even know how many of them live in the U.S., with official estimates ranging from 45 million to 200 million. Most, if not all, of them are descended from Schieffelin's initial 100 birds. The problem is that as an alien species, the starlings wreak havoc because they were introduced into an ecosystem they were not naturally part of and the local species had (and still have) no defense against them.

If you live in an area with a starling population, you are doubtless familiar with the hardy, fearless nature of these birds. They gather in enormous flocks, destroying crops, snatching food supplies from native birds, and scavenging in cities. Starlings now consume millions of dollars' worth of crops each year and cause fatal airplane crashes. Starlings also spread diseases, including e. coli infections and salmonella.

"When we try to pick out anything by itself, we find it hitched to everything else in the universe"

— John Muir

Schieffelin's starlings are a prime example of unintended consequences. In *Best Laid Plans: The Tyranny of Unintended Consequences and How to Avoid Them*, William A. Sherden writes:

Sometimes unintended consequences are catastrophic, sometimes beneficial. Occasionally their impacts are imperceptible, at other times colossal. Large events frequently have a number of unintended consequences, but even small events can trigger them. There are numerous instances of purposeful deeds completely backfiring, causing the exact opposite of what was intended.

We all know that our actions and decisions can have surprising reverberations that have no relation to our initial intentions. This is why second-order thinking is so crucial.

Sometimes we can open a Pandora's box or kick a hornet's nest without realizing it. In a dynamic world, you can never do merely one thing.

Unintended consequences arise because of the chaotic nature of systems. When Schieffelin released the starlings, he did not know the minutiae of the ecological and social systems they would be entering. As the world becomes more complicated and interconnected, the potential for ever more serious unintended consequences grows.

All too often when we mess with complicated systems, we have no more control over the outcomes than we would if we performed shamanistic dances. The simple fact is that we

cannot predict how a system will behave through mathematical models or computer simulations or basic concepts like cause and effect or supply and demand.

In *The Gene: An Intimate History*, Siddhartha Mukherjee writes that unintended consequences can be the result of scientists failing to appreciate the complexity of systems:

The parables of such scientific overreach are well-known: foreign animals, introduced to control pests, become pests in their own right; the raising of smokestacks, meant to alleviate urban pollution, releases particulate effluents higher in the air and exacerbates pollution; stimulating blood formation, meant to prevent heart attacks, thickens the blood and results in an increased risk of blood clots to the heart.

Mukherjee notes that unintended consequences can also be the result of people thinking that something is more complex than it actually is:

... when nonscientists overestimate complexity—"No one can possibly crack this code"—they fall into the trap of unanticipated consequences. In the early 1950s, a common trope among some biologists was that the genetic code would be so context dependent—so utterly determined by a particular cell in a particular organism and so horribly convoluted—that deciphering it would be impossible. The truth turned out to be quite the opposite: just one molecule carries the code, and just one code pervades the biological world. If we know the code, we can intentionally alter it in organisms, and ultimately in humans.

As was mentioned in the quote from Sherden above, sometimes perverse unintended consequences occur when actions have the opposite of the desired effect. From *The Nature of Change or the Law of Unintended Consequences* by John Mansfield:

An example of the unexpected results of change is found in the clearing of trees to make available more agricultural land. This practice has led to rising water tables and increasing salinity that eventually reduces the amount of useable land.

Some additional examples:

- Suspending problematic children from school worsens their behavior, as they are more likely to engage in criminal behavior when outside school.
- Damage-control lawsuits can lead to negative media attention and cause more harm (as occurred in the notorious *McLibel* case).

- Banning alcohol has, time and time again, led to higher consumption and the formation of criminal gangs, resulting in violent deaths.
- Abstinence-based education invariably causes a rise in teenage pregnancies.
- Many people who experience a rodent infestation will stop feeding their cats, assuming that this will encourage them to hunt more. The opposite occurs: well-fed cats are better hunters than hungry ones.
- When the British government offered financial rewards for people who killed and turned in cobras in India, people, reacting to incentives, began breeding the snakes. Once the reward program was scrapped, the population of cobras in India rose as people released the ones they had raised. The same thing occurred in Vietnam with rats.

This phenomenon, of the outcome being the opposite of the intended one, is known as “blowback” or the Cobra effect, for obvious reasons. Just as with iatrogenics, interventions often lead to worse problems.

Sometimes the consequences are mixed and take a long time to appear, as with the famous Leaning Tower of Pisa. From The Nature of Change again:

When the tower was built, it was undoubtedly intended to stand vertical. It took about 200 years to complete, but by the time the third floor was added, the poor foundations and loose subsoil had allowed it to sink on one side. Subsequent builders tried to correct this lean and the foundations have been stabilised by 20th-century engineering, but at the present time, the top of the tower is still about 15 feet (4.5 meters) from the perpendicular. Along with the unexpected failure of the foundations is the unexpected consequence of the Leaning Tower of Pisa becoming a popular tourist attraction, bringing enormous revenue to the town.

It's important to note that unintended consequences can sometimes be positive. Someone might have a child because they think parenthood will be a fulfilling experience. If their child grows up and invents a drug that saves thousands of lives, that consequence is positive yet unplanned. Pokemon Go, strange as it seemed, encouraged players to get more exercise. The creation of No Man's Lands during conflicts can preserve the habitats of local wildlife, as has occurred around the Berlin Wall. Sunken ships form coral reefs where wildlife thrives. Typically, though, when we talk about the law of unintended consequences, we're talking about negative consequences.

“Any endeavor has unintended consequences. Any ill-conceived endeavor has more.”

— Stephen Tobolowsky, The Dangerous Animals Club

The Causes of Unintended Consequences

By their nature, unintended consequences can be a mystery. I'm not a fan of the term “unintended consequences,” though, as it's too often a scapegoat for poor thinking. There are always consequences, whether you see them or not.

When we reflect on the roots of consequences that we failed to see but could have, we are liable to build a narrative that packages a series of chaotic events into a neat chain of cause and effect. A chain that means we don't have to reflect on our decisions to see where we went wrong. A chain that keeps our egos intact.

Sociologist Robert K. Merton has identified five potential causes of consequences we failed to see:

1. Our ignorance of the precise manner in which systems work.
2. Analytical errors or a failure to use Bayesian updating (not updating our beliefs in light of new information).

3. Focusing on short-term gain while forgetting long-term consequences.
4. The requirement for or prohibition of certain actions, despite the potential long-term results.
5. The creation of self-defeating prophecies (for example, due to worry about inflation, a central bank announces that it will take drastic action, thereby accidentally causing crippling *deflation* amidst the panic).

[quote]Most unintended consequences are just unanticipated consequences.[/quote]
Using logical fallacies and mental models, and keeping Schieffelin's starlings in mind, we can identify several more possible causes of consequences that we likely should have seen in advance but didn't. Here they are:

Over-reliance on models and predictions—mistaking the map for the territory. Schieffelin could have made a predictive model of how his starlings would breed and would affect their new habitat. The issue is that models are not gospel and the outcomes they predict do not represent the real world. All models are wrong, but that doesn't mean they're not useful sometimes. You have to understand the model and the terrain it's based on. Schieffelin's predictive model might have told him that the starlings' breeding habits would have a very minor impact on their new habitat. But in reality, the factors involved were too diverse and complex to take into account. Schieffelin's starlings bred faster and interacted with their new environment in ways that would be hard to predict. We can assume that he based his estimations of the future of the starlings on their behavior in their native countries.

Survivorship bias. Unintended consequences can also occur when we fail to take into account all of the available information. When predicting an outcome, we have an inherent tendency to search for other instances in which the desired result occurred. Nowadays, when anyone considers introducing a species to a new area, they are likely to hear about Schieffelin's starlings. And Schieffelin was likely influenced by stories about, perhaps even personal experiences with, successfully introducing birds into new habitats, unaware of the many ecosystem-tampering experiments that had gone horribly wrong.

The compounding effect of consequences. Unintended results do not progress in a linear manner. Just as untouched money in a savings account compounds, the population of Schieffelin's starlings compounded over the following decades. Each new bird that was hatched meant more hatchlings in future generations. At some point, the bird populations reached critical mass and no attempts to check their growth could be successful. As people in one area shot or poisoned the starlings, the breeding of those elsewhere continued.

Denial. Just as we seek out confirmatory evidence, we are inclined to deny the existence of disconfirming information. We may be in denial about the true implications of actions. Governments, in particular, tend to focus on the positive consequences of legislation while ignoring the costs. Negative unintended consequences do not always result in changes being made. Open-plan offices are another instance; they were first designed to encourage collaboration and creativity. Even though research has shown that they have the opposite effect, many companies continue to opt for open offices. They sound like a good idea, and airy offices with beanbags and pot plants might look nice, but those who continue building them are in obvious denial.

Failure to account for base rates. When we neglect to consider how the past will affect the future, we are failing to account for base rates. Schieffelin likely failed to consider the base rates of successful species introduction.

Curiosity. We sometimes perform actions out of curiosity, without any idea of the potential consequences. The problem is that our curiosity can lead us to behave in reckless,

unplanned, or poorly thought-through ways. The release of Schieffelin's starlings was in part the result of widespread curiosity about the potential for introducing European species to America.

The tendency to want to do something. We are all biased towards action. We don't want to sit around — we want to act and make changes. The problem is that sometimes doing nothing is the best route to take. In the case of Schieffelin's starlings, he was biased towards making alterations to the wildlife around him to bring Shakespeare's world to life, even though leaving nature alone is usually preferable.

Mental Models for Avoiding or Minimizing Unintended Consequences

We cannot eliminate unintended consequences, but we can become more aware of them through rational thinking techniques. In this section, we will examine some ways of working with and understanding the unexpected. Note that the examples provided here are simplifications of complex issues. The observations made about them are those of armchair critics, not those involved in the actual decision making.

Inversion. When we invert our thinking, we consider what we want to avoid, not what we want to cause. Rather than seeking perfection, we should avoid stupidity. By considering potential unintended consequences, we can then work backward. For example, the implementation of laws which required cyclists to wear helmets at all times led to a rise in fatalities. (People who feel safer behave in a more risky manner.) If we use inversion, we know we do not want any change in road safety laws to cause more injuries or deaths. So, we could consider creating stricter laws surrounding risky cycling and enforcing penalties for those who fail to follow them.

Another example is laws which aim to protect endangered animals by preventing new developments on land where rare species live. Imagine that you are a landowner, about to close a lucrative deal. You look out at your land and notice a smattering of endangered wildflowers. Do you cancel the sale and leave the land to the flowers? Of course not. Unless you are exceptionally honest, you grab a spade, dig up the flowers, and keep them a secret. Many people shoot, poison, remove, or otherwise harm endangered animals and plants. If lawmakers used inversion, they would recognize that they want to avoid those consequences and work backward.

[quote]We have to focus on avoiding the worst unintended consequences, rather than on controlling everything.[/quote]

Looking for disconfirming evidence. Instead of looking for information that confirms that our actions will have the desired consequences, we should rigorously search for evidence that they will not. How did this go in the past? Take the example of laws regarding the minimum wage and worker rights. Every country has people pushing for a higher minimum wage and for more protection of workers. If we search for disconfirming evidence, we see that these laws can do more harm than good. The French appear to have perfected labor laws. All employees are, on the face of it, blessed with a minimum wage of 17,764 euros per year, a 35-hour work week, five weeks paid holiday, and strict protection against redundancy (layoffs). So, why don't we all just move to France? Because these measures result in a lot of negative unintended consequences. Unemployment rates are high, as many businesses cannot afford to hire many employees. Foreign companies are reluctant to hire French workers, as they can't fire them during tough economic times. Everyone deserves a fair minimum wage and protection from abuse of their rights, but France illustrates how taking this principle too far can have negative unintended consequences.

Understanding our circle of competence. Each of us has areas we understand well and are familiar with. When we act outside our circle of competence, we increase the risk of unintended consequences. If you decide to fix your boiler without consulting a plumber, you are acting outside of your circle of competence and have a good chance of making the problem worse. When the British government implemented bounties for dead cobras in India, their circle of competence did not include an understanding of the locals. Perhaps if

they had consulted some Indian people and asked how they would react to such a law, they could have avoided causing a rise in the cobra population.

Second-order thinking. We often forget that our actions can have two layers of consequences, of which the first might be intended and the second unintended. With Schieffelin's starlings, the first layer of consequences was positive and as intended. The birds survived and bred, and Shakespeare fans living in New York got to feel a bit closer to the iconic playwright. But the negative second layer of consequences dwarfed the first layer. For the parents of a child who grows up to invent a life-saving drug, the first layer of consequences is that those parents (presumably) have a fulfilling experience. The second layer of consequences is that lives are saved. When we use second-order thinking, we ask: what could happen? What if the opposite of what I expect happens? What might the results be a year, five years, or a decade from now?

Most unintended consequences are just unanticipated consequences. And in the world of consequences intentions often don't matter. Intentions, after all, only apply to *positive* anticipated consequences. Only in rare circumstances would someone intend to cause negative consequences.

So when we make decisions we must ask what the consequences be? This is where having a toolbox of mental models becomes helpful.

128. Half Life: The Decay of Knowledge and What to Do About It

Understanding the concept of a half-life will change what you read and how you invest your time. It will explain why our careers are increasingly specialized and offer a look into how we can compete more effectively in a very crowded world.

The Basics

A half-life is the time taken for something to halve its quantity. The term is most often used in the context of radioactive decay, which occurs when unstable atomic particles lose energy. Twenty-nine elements are known to be capable of undergoing this process. Information also has a half-life, as do drugs, marketing campaigns, and all sorts of other things. We see the concept in any area where the quantity or strength of something decreases over time.

Radioactive decay is random, and measured half-lives are based on the most probable rate. We know that a nucleus will decay at some point; we just cannot predict when. It could be anywhere between instantaneous and the total age of the universe. Although scientists have defined half-lives for different elements, the exact rate is completely random.

Half-lives of elements vary tremendously. For example, carbon takes millions of years to decay; that's why it is stable enough to be a component of the bodies of living organisms. Different isotopes of the same element can also have different half-lives.

Three main types of nuclear decay have been identified: alpha, beta, and gamma. Alpha decay occurs when a nucleus splits into two parts: a helium nucleus and the remainder of the original nucleus. Beta decay occurs when a neutron in the nucleus of an element changes into a proton. The result is that it turns into a different element, such as when potassium decays into calcium. Beta decay also releases a neutrino — a particle with virtually no mass. If a nucleus emits radiation without experiencing a change in its composition, it is subject to gamma decay. Gamma radiation contains an enormous amount of energy.

The Discovery of Half-Lives

The discovery of half-lives (and alpha and beta radiation) is credited to Ernest Rutherford, one of the most influential physicists of his time. Rutherford was at the forefront of this major discovery when he worked with physicist Joseph John Thompson on complementary experiments leading to the discovery of electrons. Rutherford recognized the potential of what he was observing and began researching radioactivity. Two years later, he identified the distinction between alpha and beta rays. This led to his discovery of half-lives, when he noticed that samples of radioactive materials took the same amount of time to decay by half. By 1902, Rutherford and his collaborators had a coherent theory of radioactive decay (which they called “atomic disintegration”). They demonstrated that radioactive decay enabled one element to turn into another — research which would earn Rutherford a Nobel Prize. A year later, he spotted the missing piece in the work of the chemist Paul Villard and named the third type of radiation gamma.

Half-lives are based on probabilistic thinking. If the half-life of an element is seven days, it is most probable that half of the atoms will have decayed in that time. For a large number of atoms, we can expect half-lives to be fairly consistent. It's important to note that radioactive decay is based on the element itself, not the quantity of it. By contrast, in other situations, the half-life may vary depending on the amount of material. For example, the half-life of a chemical someone ingests might depend on the quantity.

In biology, a half-life is the time taken for a substance to lose half its effects. The most obvious instance is drugs; the half-life is the time it takes for their effect to halve, or for half of the substance to leave the body. The half-life of caffeine is around 6 hours, but (as with most biological half-lives) numerous factors can alter that number. People with compromised liver function or certain genes will take longer to metabolize caffeine.

Consumption of grapefruit juice has been shown in some studies to slow caffeine metabolism. It takes around 24 hours for a dose of caffeine to fully leave the body. The half-lives of drugs vary from a few seconds to several weeks. To complicate matters, biological half-lives vary for different parts of the body. Lead has a half-life of around a month in the blood, but a decade in bone. Plutonium in bone has a half-life of a century — more than double the time for the liver.

Marketers refer to the half-life of a campaign — the time taken to receive half the total responses. Unsurprisingly, this time varies among media. A paper catalog may have a half-life of about three weeks, whereas a tweet might have a half-life of a few minutes. Calculating this time is important for establishing how frequently a message should be sent.

“Every day that we read the news we have the possibility of being confronted with a fact about our world that is wildly different from what we thought we knew.”

— Samuel Arbesman

The Half-Life of Facts

In *The Half-Life of Facts: Why Everything We Know Has an Expiration Date*, Samuel Arbesman (see our [Knowledge Project interview](#)) posits that facts decay over time until they are no longer facts or perhaps no longer complete. According to Arbesman, information has a predictable half-life: the time taken for half of it to be replaced or disproved. Over time, one group of facts replaces another. As our tools and knowledge become more advanced, we can discover more — sometimes new things that contradict what we thought we knew, sometimes nuances about old things. Sometimes we discover a whole area that we didn’t know about.

The rate of these discoveries varies. Our body of engineering knowledge changes more slowly, for example, than does our body of psychological knowledge.

Arbesman studied the nature of facts. The field was born in 1947, when mathematician Derek J. de Solla Price was arranging a set of philosophical books on his shelf. Price noted something surprising: the sizes of the books fit an exponential curve. His curiosity piqued, he began to see whether the same curve applied to science as a whole. Price established that the quantity of scientific data available was doubling every 15 years. This meant that some of the information had to be rendered obsolete with time.

Scientometrics shows us that facts are always changing, and much of what we know is (or soon will be) incorrect. Indeed, much of the available published research, however often it is cited, has never been reproduced and cannot be considered true. In a controversial paper entitled “Why Most Published Research Findings Are False,” John Ioannides covers the rampant nature of poor science. Many researchers are incentivized to find results that will please those giving them funding. Intense competition makes it essential to find new information, even if it is found in a dubious manner. Yet we all have a tendency to turn a blind eye when beliefs we hold dear are disproved and to pay attention only to information confirming our existing opinions.

As an example, Arbesman points to the number of chromosomes in a human cell. Up until 1965, 48 was the accepted number that medical students were taught. (In 1953, it had been declared an established fact by a leading cytologist). Yet in 1956, two researchers, Joe Hin Tjio and Albert Levan, made a bold assertion. They declared the true number to be 46. During their research, Tjio and Levan could never find the number of chromosomes they expected. Discussing the problem with their peers, they discovered they were not alone. Plenty of other researchers found themselves two chromosomes short of the expected 48. Many researchers even abandoned their work because of this perceived error. But Tjio and Levan were right (for now, anyway). Although an extra two chromosomes seems like a minor mistake, we don’t know the opportunity costs of the time

researchers invested in faulty hypotheses or the value of the work that was abandoned. It was an emperor's-new-clothes situation, and anyone counting 46 chromosomes assumed they were the ones making the error.

As Arbesman puts it, facts change incessantly. Many of us have seen the ironic (in hindsight) doctor-endorsed cigarette ads from the past. A glance at a newspaper will doubtless reveal that meat or butter or sugar has gone from deadly to saintly, or vice versa. We forget that laughable, erroneous beliefs people once held are not necessarily any different from those we now hold. The people who believed that the earth was the center of the universe, or that some animals appeared out of nowhere or that the earth was flat, were not stupid. They just believed facts that have since decayed. Arbesman gives the example of a dermatology test that had the same question two years running, with a different answer each time. This is unsurprising considering the speed at which our world is changing.

As Arbesman points out, in the last century the world's population has swelled from 2 billion to 7 billion, we have taken on space travel, and we have altered the very definition of science.

Our world seems to be in constant flux. With our knowledge changing all the time, even the most informed people can barely keep up. All this change may seem random and overwhelming (Dinosaurs have feathers? When did that happen?), but it turns out there is actually order within the shifting noise. This order is regular and systematic and is one that can be described by science and mathematics.

The order Arbesman describes mimics the decay of radioactive elements. Whenever new information is discovered, we can be sure it will break down and be proved wrong at some point. As with a radioactive atom, we don't know precisely when that will happen, but we know it will occur at some point.

If we zoom out and look at a particular body of knowledge, the random decay becomes orderly. Through probabilistic thinking, we can predict the half-life of a group of facts with the same certainty with which we can predict the half-life of a radioactive atom. The problem is that we rarely consider the half-life of information. Many people assume that whatever they learned in school remains true years or decades later. Medical students who learned in university that cells have 48 chromosomes would not learn later in life that this is wrong unless they made an effort to do so.

OK, so we know that our knowledge will decay. What do we do with this information? Arbesman says,

... simply knowing that knowledge changes like this isn't enough. We would end up going a little crazy as we frantically tried to keep up with the ever changing facts around us, forever living on some sort of informational treadmill. But it doesn't have to be this way because there are patterns. Facts change in regular and mathematically understandable ways. And only by knowing the pattern of our knowledge evolution can we be better prepared for its change.

Recent initiatives have sought to calculate the half-life of an academic paper. Ironically, academic journals have largely neglected research into how people use them and how best to fund the efforts of researchers. Research by Philip Davis shows the time taken for a paper to receive half of its total downloads. Davis's results are compelling. While most forms of media have a half-life measured in days or even hours, 97 percent of academic papers have a half-life longer than a year. Engineering papers have a slightly shorter half-life than other fields of research, with double the average (6 percent) having a half-life of under a year. This makes sense considering what we looked at earlier in this post. Health and medical publications have the shortest overall half-life: two to three years. Physics, mathematics, and humanities publications have the longest half-lives: two to four years.

The Half-Life of Secrets

According to Peter Swire, writing in "[The Declining Half-Life of Secrets](#)," the half-life of secrets (by which Swire generally means classified information) is shrinking. In the past, a government secret could be kept for over 25 years. Nowadays, hacks and leaks have shrunk that time considerably. Swire writes:

During the Cold War, the United States developed the basic classification system that exists today. Under Executive Order 13526, an executive agency must declassify its documents after 25 years unless an exception applies, with stricter rules if documents stay classified for 50 years or longer. These time frames are significant, showing a basic mind-set of keeping secrets for a time measured in decades.

Swire notes that there are three main causes: "the continuing effects of Moore's Law — or the idea that computing power doubles every two years, the sociology of information technologists, and the different source and methods for signals intelligence today compared with the Cold War." One factor is that spreading leaked information is easier than ever. In the past, it was often difficult to get information published. Newspapers feared legal repercussions if they shared classified information. Anyone can now release secret information, often anonymously, as with WikiLeaks. Governments cannot as easily rely on media gatekeepers to cover up leaks.

Rapid changes in technology or geopolitics often reduce the value of classified information, so the value of some, but not all, classified information also has a half-life. Sometimes it's days or weeks, and sometimes it's years. For some secrets, it's not worth investing the massive amount of computer time that would be needed to break them because by the time you crack the code, the information you wanted to know might have expired.

(As an aside, if you were to [invert the problem](#) of all these credit card and SSN leaks, you might conclude that reducing the value of possessing this information would be more effective than spending money to secure it.)

"Our policy (at Facebook) is literally to hire as many talented engineers as we can find. The whole limit in the system is that there are not enough people who are trained and have these skills today."

— Mark Zuckerberg

The Half-Lives of Careers and Business Models

The issue with information having a half-life should be obvious. Many fields depend on individuals with specialized knowledge, learned through study or experience or both. But what if those individuals are failing to keep up with changes and clinging to outdated facts? What if your doctor is offering advice that has been rendered obsolete since they finished medical school? What if your own degree or qualifications are actually useless? These are real problems, and knowing about half-lives will help you make yourself more adaptable. While figures for the half-lives of most knowledge-based careers are hard to find, we do know the half-life of an engineering career. A century ago, it would take 35 years for half of what an engineer learned when earning their degree to be disproved or replaced. By the 1960s, that time span shrank to a mere decade. Today that figure is probably even lower. In 1966 paper entitled "The Dollars and Sense of Continuing Education," Thomas Jones calculated the effort that would be required for an engineer to stay up to date, assuming a 10-year half-life. According to Jones, an engineer would need to devote at least five hours per week, 48 weeks a year, to stay up to date with new advancements. A typical degree requires about 4800 hours of work. Within 10 years, the information learned during 2400 of those hours would be obsolete. The five-hour figure does not include the time necessary to revise forgotten information that is still relevant. A 40-year career as an engineer would require 9600 hours of independent study.

Keep in mind that Jones made his calculations in the 1960s. Modern estimates place the half-life of an engineering degree at between 2.5 and 5 years, requiring between 10 and 20 hours of study per week. Welcome to the treadmill, where you have to run faster and faster so that you don't fall behind.

Unsurprisingly, putting in this kind of time is simply impossible for most people. The result is an ever-shrinking length of a typical engineer's career and a bias towards hiring recent graduates. A partial escape from this time-consuming treadmill that offers little progress is to recognize the continuous need for learning. If you agree with that, it becomes easier to place time and emphasis on developing heuristics and systems to foster learning. The faster the pace of knowledge change, the more valuable the skill of learning becomes. A study by PayScale found that the median age of workers in most successful technology companies is substantially lower than that of other industries. Of 32 companies, just six had a median worker age above 35, despite the average across all workers being just over 42. Eight of the top companies had a median worker age of 30 or below — 28 for Facebook, 29 for Google, and 26 for Epic Games. The upshot is that salaries are high for those who can stay current while gaining years of experience.

In a similar vein, business models have ever shrinking half-lives. The nature of capitalism is that you have to be better last year than you were this year — not to gain market share but to maintain what you already have. If you want to get ahead, you need asymmetry; otherwise, you get lost in trench warfare. How long would it take for half of Uber or Facebook's business models to be irrelevant? It's hard to imagine it being more than a couple of years or even months.

In *The Business Model Innovation Factory: How to Stay Relevant When the World Is Changing*, Saul Kaplan highlights the changing half-lives of business models. In the past, models could last for generations. The majority of CEOs oversaw a single business for their entire careers. Business schools taught little about agility or pivoting. Kaplan writes: *During the industrial era once the basic rules for how a company creates, delivers, and captures value were established[,] they became etched in stone, fortified by functional silos, and sustained by reinforcing company cultures. All of a company's DNA, energy, and resources were focused on scaling the business model and beating back competition attempting to do a better job executing the same business model. Companies with nearly identical business models slugged it out for market share within well-defined industry sectors.*

[...]

Those days are over. The industrial era is not coming back. The half-life of a business model is declining. Business models just don't last as long as they used to. In the twenty-first century business leaders are unlikely to manage a single business for an entire career. Business leaders are unlikely to hand down their businesses to the next generation of leaders with the same business model they inherited from the generation before.

The Burden of Knowledge

The flip side of a half-life is the time it takes to double something. A useful guideline to calculate the time it takes for something to double is to divide 70 by the rate of growth. This formula isn't perfect, but it gives a good indication. Known as the Rule of 70, it applies only to exponential growth when the relative growth rate remains consistent, such as with compound interest.

The higher the rate of growth, the shorter the doubling time. For example, if the population of a city is increasing by 2 percent per year, we divide 70 by 2 to get a doubling time of 35 years. The rule of 70 is a useful heuristic; population growth of 2 percent might seem low, but your perspective might change when you consider that the city's population could double in just 35 years. The Rule of 70 can also be used to calculate the time for an investment to double in value; for example, \$100 at 7 percent compound interest will double in just a decade and quadruple in 20 years. The average newborn baby doubles its

birth weight in under four months. The average doubling time for a tumor is also four months.

We can see how information changes in the figures for how long it takes for a body of knowledge to double in size. The figures quoted by Arbesman (drawn from *Little Science, Big Science ... and Beyond* by Derek J. de Solla Price) are compelling, including:

- Time for the number of entries in a dictionary of national biographies to double: 100 years
- Time for the number of universities to double: 50 years
- Time for the number of known chemical compounds to double: 15 years
- Time for the number of known asteroids to double: 10 years

Arbesman also gives figures for the time taken for the available knowledge in a particular field to double, including:

- Medicine: 87 years
- Mathematics: 63 years
- Chemistry: 35 years
- Genetics: 32 years

The doubling of knowledge increases the learning load over time. As a body of knowledge doubles so does the cost of wrapping your head around what we already know. This cost is the burden of knowledge. To be the best in a general field today requires that you know more than the person who was the best only 20 years ago. Not only do you have to be better to be the best, but you also have to be better just to stay in the game.

The corollary is that because there is so much to know, we specialize in very niche areas. This makes it easier to grasp the existing body of facts, keep up to date on changes, and rise to the level of expert. The problem is that specializing also makes it easier to see the world through the narrow focus of your specialty, makes it harder to work with other people (as niches are often dominated by jargon), and makes you prone to overvalue the new and novel.

Conclusion

As we have seen, understanding how half-lives work has numerous practical applications, from determining when radioactive materials will become safe to figuring out effective drug dosages. Half-lives also show us that if we spend time learning something that changes quickly, we might be wasting our time. Like Alice in Wonderland — and a perfect example of the Red Queen Effect — we have to run faster and faster just to keep up with where we are. So if we want our knowledge to compound, we'll need to focus on the invariant general principles.

129. First Principles: The Building Blocks of True Knowledge

First-principles thinking is one of the best ways to reverse-engineer complicated problems and unleash creative possibility. Sometimes called “reasoning from first principles,” the idea is to break down complicated problems into basic elements and then reassemble them from the ground up. It’s one of the best ways to learn to think for yourself, unlock your creative potential, and move from linear to non-linear results.

This approach was used by the philosopher Aristotle and is used now by Elon Musk and Charlie Munger. It allows them to cut through the fog of shoddy reasoning and inadequate analogies to see opportunities that others miss.

I don’t know what’s the matter with people: they don’t learn by understanding; they learn by some other way—by rote or something. Their knowledge is so fragile!

Richard Feynman

The Basics

A first principle is a foundational proposition or assumption that stands alone. We cannot deduce first principles from any other proposition or assumption.

Aristotle, writing^[1] on first principles, said:

In every systematic inquiry (methodos) where there are first principles, or causes, or elements, knowledge and science result from acquiring knowledge of these; for we think we know something just in case we acquire knowledge of the primary causes, the primary first principles, all the way to the elements.

Later he connected the idea to knowledge, defining first principles as “the first basis from which a thing is known.”^[2]

The search for first principles is not unique to philosophy. All great thinkers do it. Reasoning by first principles removes the impurity of assumptions and conventions. What remains is the essentials. It's one of the best mental models you can use to improve your thinking because the essentials allow you to see where reasoning by analogy might lead you astray.

The Coach and the Play Stealer

My friend Mike Lombardi (a former NFL executive) and I were having dinner in L.A. one night, and he said, "Not everyone that's a coach is really a coach. Some of them are just play stealers."

Every play we see in the NFL was at some point created by someone who thought, "What would happen if the players did this?" and went out and tested the idea. Since then, thousands, if not millions, of plays have been created. That's part of what coaches do.

They assess what's physically possible, along with the weaknesses of the other teams and the capabilities of their own players, and create plays that are designed to give their teams an advantage.

The coach reasons from first principles. The rules of football are the first principles: they govern what you can and can't do. Everything is possible as long as it's not against the rules.

The play stealer works off what's already been done. Sure, maybe he adds a tweak here or there, but by and large he's just copying something that someone else created.

While both the coach and the play stealer start from something that already exists, they generally have different results. These two people look the same to most of us on the sidelines or watching the game on the TV. Indeed, they look the same most of the time, but when something goes wrong, the difference shows. Both the coach and the play stealer call successful plays and unsuccessful plays. Only the coach, however, can determine why a play was successful or unsuccessful and figure out how to adjust it. The coach, unlike the play stealer, understands what the play was designed to accomplish and where it went wrong, so he can easily course-correct. The play stealer has no idea what's going on. He doesn't understand the difference between something that didn't work and something that played into the other team's strengths.

Musk would identify the play stealer as the person who reasons by analogy, and the coach as someone who reasons by first principles. When you run a team, you want a coach in charge and not a play stealer. (If you're a sports fan, you need only look at the difference between the Cleveland Browns and the New England Patriots.)

We're all somewhere on the spectrum between coach and play stealer. We reason by first principles, by analogy, or a blend of the two.

Another way to think about this distinction comes from another friend, Tim Urban. He says^[3] it's like the difference between the cook and the chef. While these terms are often used interchangeably, there is an important nuance. The chef is a trailblazer, the person who invents recipes. He knows the raw ingredients and how to combine them. The cook, who reasons by analogy, uses a recipe. He creates something, perhaps with slight variations, that's already been created.

The difference between reasoning by first principles and reasoning by analogy is like the difference between being a chef and being a cook. If the cook lost the recipe, he'd be screwed. The chef, on the other hand, understands the flavor profiles and combinations at such a fundamental level that he doesn't even use a recipe. He has real knowledge as opposed to know-how.

Authority

So much of what we believe is based on some authority figure telling us that something is true. As children, we learn to stop questioning when we're told "Because I said so." (More on this later.) As adults, we learn to stop questioning when people say "Because that's how it works." The implicit message is "understanding be damned — shut up and stop bothering me." It's not intentional or personal. OK, sometimes it's personal, but most of the time, it's not.

If you outright reject dogma, you often become a problem: a student who is always pestering the teacher. A kid who is always asking questions and never allowing you to cook dinner in peace. An employee who is always slowing things down by asking why. When you can't change your mind, though, you die. Sears was once thought indestructible before Wal-Mart took over. Sears failed to see the world change. Adapting to change is an incredibly hard thing to do when it comes into conflict with the very thing that caused so much success. As Upton Sinclair aptly pointed out, "It is difficult to get a man to understand something, when his salary depends on his not understanding it." Wal-Mart failed to see the world change and is now under assault from Amazon.

If we never learn to take something apart, test the assumptions, and reconstruct it, we end up trapped in what other people tell us — trapped in the way things have always been done. When the environment changes, we just continue as if things were the same.

First-principles reasoning cuts through dogma and removes the blinders. We can see the world as it is and see what is possible.

When it comes down to it, everything that is not a law of nature is just a shared belief.

Money is a shared belief. So is a border. So are bitcoins. The list goes on.

Some of us are naturally skeptical of what we're told. Maybe it doesn't match up to our experiences. Maybe it's something that used to be true but isn't true anymore. And maybe we just think very differently about something.

"To understand is to know what to do."

— Wittgenstein

Techniques for Establishing First Principles

There are many ways to establish first principles. Let's take a look at a few of them.

Socratic Questioning

Socratic questioning can be used to establish first principles through stringent analysis.

This a disciplined questioning process, used to establish truths, reveal underlying assumptions, and separate knowledge from ignorance. The key distinction between Socratic questioning and normal discussions is that the former seeks to draw out first principles in a systematic manner. Socratic questioning generally follows this process:

1. Clarifying your thinking and explaining the origins of your ideas (Why do I think this? What exactly do I think?)
2. Challenging assumptions (How do I know this is true? What if I thought the opposite?)
3. Looking for evidence (How can I back this up? What are the sources?)
4. Considering alternative perspectives (What might others think? How do I know I am correct?)
5. Examining consequences and implications (What if I am wrong? What are the consequences if I am?)
6. Questioning the original questions (Why did I think that? Was I correct? What conclusions can I draw from the reasoning process?)

This process stops you from relying on your gut and limits strong emotional responses.

This process helps you build something that lasts.

"Because I Said So" or "The Five Whys"

Children instinctively think in first principles. Just like us, they want to *understand* what's happening in the world. To do so, they intuitively break through the fog with a game some parents have come to hate.

"Why?"

"Why?"

"Why?"

Here's an example that has played out numerous times at my house:

"It's time to brush our teeth and get ready for bed."

"Why?"

"Because we need to take care of our bodies, and that means we need sleep."

"Why do we need sleep?"

"Because we'd die if we never slept."

"Why would that make us die?"

"I don't know; let's go look it up."

Kids are just trying to understand why adults are saying something or why they want them to do something.

The first time your kid plays this game, it's cute, but for most teachers and parents, it eventually becomes annoying. Then the answer becomes what my mom used to tell me: "Because I said so!" (Love you, Mom.)

Of course, I'm not always that patient with the kids. For example, I get testy when we're late for school, or we've been travelling for 12 hours, or I'm trying to fit too much into the time we have. Still, I try never to say "Because I said so."

People hate the "because I said so" response for two reasons, both of which play out in the corporate world as well. The first reason we hate the game is that we feel like it slows us down. We know what we want to accomplish, and that response creates unnecessary drag. The second reason we hate this game is that after one or two questions, we are often lost. We actually don't know why. Confronted with our own ignorance, we resort to self-defense.

I remember being in meetings and asking people why we were doing something this way or why they thought something was true. At first, there was a mild tolerance for this approach. After three "whys," though, you often find yourself on the other end of some version of "we can take this offline."

Can you imagine how that would play out with Elon Musk? Richard Feynman? Charlie Munger? Musk would build a billion-dollar business to prove you wrong, Feynman would think you're an idiot, and Munger would profit based on your inability to think through a problem.

"Science is a way of thinking much more than it is a body of knowledge."

— Carl Sagan

Examples of First Principles in Action

So we can better understand how first-principles reasoning works, let's look at four examples.

Elon Musk and SpaceX

Perhaps no one embodies first-principles thinking more than Elon Musk. He is one of the most audacious entrepreneurs the world has ever seen. My kids (grades 3 and 2) refer to him as a real-life Tony Stark, thereby conveniently providing a good time for me to remind them that by fourth grade, Musk was reading the Encyclopedia Britannica and not Pokemon.

What's most interesting about Musk is not what he thinks but how he thinks:

I think people's thinking process is too bound by convention or analogy to prior experiences. It's rare that people try to think of something on a first principles basis. They'll say, "We'll do that because it's always been done that way." Or they'll not do it because "Well, nobody's ever done that, so it must not be good. But that's just a ridiculous way to think. You have to build up the reasoning from the ground up—"from the first principles" is the phrase that's used in physics. You look at the fundamentals and construct your reasoning from that, and then you see if you have a conclusion that works or doesn't work, and it may or may not be different from what people have done in the past.[4]

His approach to understanding reality is to start with what is true — not with his intuition. The problem is that we don't know as much as we think we do, so our intuition isn't very good. We trick ourselves into thinking we know what's possible and what's not. The way Musk thinks is much different.

Musk starts out with something he wants to achieve, like building a rocket. Then he starts with the first principles of the problem. Running through how Musk would think, Larry Page said in an

interview, “What are the physics of it? How much time will it take? How much will it cost? How much cheaper can I make it? There’s this level of engineering and physics that you need to make judgments about what’s possible and interesting. Elon is unusual in that he knows that, and he also knows business and organization and leadership and governmental issues.”[5]

Rockets are absurdly expensive, which is a problem because Musk wants to send people to Mars. And to send people to Mars, you need cheaper rockets. So he asked himself, “What is a rocket made of? Aerospace-grade aluminum alloys, plus some titanium, copper, and carbon fiber. And ... what is the value of those materials on the commodity market? It turned out that the materials cost of a rocket was around two percent of the typical price.”

[6]

Why, then, is it so expensive to get a rocket into space? Musk, a notorious self-learner with degrees in both economics and physics, literally taught himself rocket science. He figured that the only reason getting a rocket into space is so expensive is that people are stuck in a mindset that doesn’t hold up to first principles. With that, Musk decided to create SpaceX and see if he could build rockets himself from the ground up.

In an interview with Kevin Rose, Musk summarized his approach:

I think it’s important to reason from first principles rather than by analogy. So the normal way we conduct our lives is, we reason by analogy. We are doing this because it’s like something else that was done, or it is like what other people are doing... with slight iterations on a theme. And it’s ... mentally easier to reason by analogy rather than from first principles. First principles is kind of a physics way of looking at the world, and what that really means is, you ... boil things down to the most fundamental truths and say, “okay, what are we sure is true?” ... and then reason up from there. That takes a lot more mental energy.[7]

Musk then gave an example of how Space X uses first principles to innovate at low prices: *Somebody could say — and in fact people do — that battery packs are really expensive and that’s just the way they will always be because that’s the way they have been in the past. ... Well, no, that’s pretty dumb... Because if you applied that reasoning to anything new, then you wouldn’t be able to ever get to that new thing.... you can’t say, ... “oh, nobody wants a car because horses are great, and we’re used to them and they can eat grass and there’s lots of grass all over the place and ... there’s no gasoline that people can buy....”*

He then gives a fascinating example about battery packs:

... they would say, “historically, it costs \$600 per kilowatt-hour. And so it’s not going to be much better than that in the future. ... So the first principles would be, ... what are the material constituents of the batteries? What is the spot market value of the material constituents? ... It’s got cobalt, nickel, aluminum, carbon, and some polymers for separation, and a steel can. So break that down on a material basis; if we bought that on a London Metal Exchange, what would each of these things cost? Oh, jeez, it’s ... \$80 per kilowatt-hour. So, clearly, you just need to think of clever ways to take those materials and combine them into the shape of a battery cell, and you can have batteries that are much, much cheaper than anyone realizes.

BuzzFeed

After studying the psychology of virality, Jonah Peretti founded BuzzFeed in 2006. The site quickly grew to be one of the most popular on the internet, with hundreds of employees and substantial revenue.

Peretti figured out early on the first principle of a successful website: wide distribution. Rather than publishing articles people should read, BuzzFeed focuses on publishing those that people want to read. This means aiming to garner maximum social shares to put distribution in the hands of readers.

Peretti recognized the first principles of online popularity and used them to take a new approach to journalism. He also ignored SEO, saying, “Instead of making content robots like, it was more satisfying to make content humans want to share.”[8] Unfortunately for us, we share a lot of cat videos.

A common aphorism in the field of viral marketing is, “content might be king, but distribution is queen, and she wears the pants” (or “and she has the dragons”; pick your metaphor). BuzzFeed’s distribution-based approach is based on obsessive measurement, using A/B testing and analytics.

Jon Steinberg, president of BuzzFeed, explains the first principles of virality:

Keep it short. Ensure [that] the story has a human aspect. Give people the chance to engage. And let them react. People mustn’t feel awkward sharing it. It must feel authentic. Images and lists work. The headline must be persuasive and direct.

Derek Sivers and CD Baby

When Sivers founded his company CD Baby, he reduced the concept down to first principles. Sivers asked, What does a successful business need? His answer was happy customers.

Instead of focusing on garnering investors or having large offices, fancy systems, or huge numbers of staff, Sivers focused on making each of his customers happy. An example of this is his famous order confirmation email, part of which reads:

Your CD has been gently taken from our CD Baby shelves with sterilized contamination-free gloves and placed onto a satin pillow. A team of 50 employees inspected your CD and polished it to make sure it was in the best possible condition before mailing. Our packing specialist from Japan lit a candle and a hush fell over the crowd as he put your CD into the finest gold-lined box money can buy.

By ignoring unnecessary details that cause many businesses to expend large amounts of money and time, Sivers was able to rapidly grow the company to \$4 million in monthly revenue. In *Anything You Want*, Sivers wrote:

Having no funding was a huge advantage for me.

A year after I started CD Baby, the dot-com boom happened. Anyone with a little hot air and a vague plan was given millions of dollars by investors. It was ridiculous. ...

Even years later, the desks were just planks of wood on cinder blocks from the hardware store. I made the office computers myself from parts. My well-funded friends would spend \$100,000 to buy something I made myself for \$1,000. They did it saying, “We need the very best,” but it didn’t improve anything for their customers. ...

It’s counterintuitive, but the way to grow your business is to focus entirely on your existing customers. Just thrill them, and they’ll tell everyone.

To survive as a business, you need to treat your customers well. And yet so few of us master this principle.

Employing First Principles in Your Daily Life

Most of us have no problem thinking about what we want to achieve in life, at least when we’re young. We’re full of big dreams, big ideas, and boundless energy. The problem is that we let others tell us what’s possible, not only when it comes to our dreams but also when it comes to how we go after them. And when we let other people tell us what’s possible or what the best way to do something is, we outsource our thinking to someone else.

The real power of first-principles thinking is moving away from incremental improvement and into possibility. Letting others think for us means that we’re using their analogies, their conventions, and their possibilities. It means we’ve inherited a world that conforms to what they think. This is incremental thinking.

When we take what already exists and improve on it, we are in the shadow of others. It’s only when we step back, ask ourselves what’s possible, and cut through the flawed analogies that we see what is possible. Analogies are beneficial; they make complex

problems easier to communicate and increase understanding. Using them, however, is not without a cost. They limit our beliefs about what's possible and allow people to argue without ever exposing our (faulty) thinking. Analogies move us to see the problem in the same way that someone else sees the problem.

The gulf between what people currently see because their thinking is framed by someone else and what is physically possible is filled by the people who use first principles to think through problems.

First-principles thinking clears the clutter of what we've told ourselves and allows us to rebuild from the ground up. Sure, it's a lot of work, but that's why so few people are willing to do it. It's also why the rewards for filling the chasm between possible and incremental improvement tend to be non-linear.

Let's take a look at a few of the limiting beliefs that we tell ourselves.

"I don't have a good memory." [10]

People have far better memories than they think they do. Saying you don't have a good memory is just a convenient excuse to let you forget. Taking a first-principles approach means asking how much information we can physically store in our minds. The answer is "a lot more than you think." Now that we know it's possible to put more into our brains, we can reframe the problem into finding the most optimal way to store information in our brains.

"There is too much information out there."

A lot of professional investors read Farnam Street. When I meet these people and ask how they consume information, they usually fall into one of two categories. The differences between the two apply to all of us. The first type of investor says there is too much information to consume. They spend their days reading every press release, article, and blogger commenting on a position they hold. They wonder what they are missing. The second type of investor realizes that reading everything is unsustainable and stressful and makes them prone to overvaluing information they've spent a great amount of time consuming. These investors, instead, seek to understand the variables that will affect their investments. While there might be hundreds, there are usually three to five variables that will really move the needle. The investors don't have to read everything; they just pay attention to these variables.

"All the good ideas are taken."

A common way that people limit what's possible is to tell themselves that all the good ideas are taken. Yet, people have been saying this for hundreds of years — literally — and companies keep starting and competing with different ideas, variations, and strategies.

"We need to move first."

I've heard this in boardrooms for years. The answer isn't as black and white as this statement. The iPhone wasn't first, it was better. Microsoft wasn't the first to sell operating systems; it just had a better business model. There is a lot of evidence showing that first movers in business are more likely to fail than latecomers. Yet this myth about the need to move first continues to exist.

Sometimes the early bird gets the worm and sometimes the first mouse gets killed. You have to break each situation down into its component parts and see what's possible. That is the work of first-principles thinking.

"I can't do that; it's never been done before."

People like Elon Musk are constantly doing things that have never been done before. This type of thinking is analogous to looking back at history and building, say, floodwalls, based on the worst flood that has happened before. A better bet is to look at what could happen and plan for that.

"As to methods, there may be a million and then some, but principles are few. The man who grasps principles can successfully select his own methods. The man who tries methods, ignoring principles, is sure to have trouble."

— Harrington Emerson

Conclusion

The thoughts of others imprison us if we're not thinking for ourselves.

Reasoning from first principles allows us to step outside of history and conventional wisdom and see what is possible. When you really understand the principles at work, you can decide if the existing methods make sense. Often they don't.

Reasoning by first principles is useful when you are (1) doing something for the first time, (2) dealing with complexity, and (3) trying to understand a situation that you're having problems with. In all of these areas, your thinking gets better when you stop making assumptions and you stop letting others frame the problem for you.

Analogies can't replace understanding. While it's easier on your brain to reason by analogy, you're more likely to come up with better answers when you reason by first principles. This is what makes it one of the best sources of creative thinking. Thinking in first principles allows you to adapt to a changing environment, deal with reality, and seize opportunities that others can't see.

Many people mistakenly believe that creativity is something that only some of us are born with, and either we have it or we don't. Fortunately, there seems to be ample evidence that this isn't true.^[11] We're all born rather creative, but during our formative years, it can be beaten out of us by busy parents and teachers. As adults, we rely on convention and what we're told because that's easier than breaking things down into first principles and thinking for ourselves. Thinking through first principles is a way of taking off the blinders. Most things suddenly seem more possible.

"I think most people can learn a lot more than they think they can," says Musk. "They sell themselves short without trying. One bit of advice: it is important to view knowledge as sort of a semantic tree — make sure you understand the fundamental principles, i.e., the trunk and big branches, before you get into the leaves/details or there is nothing for them to hang on to."

130. Reversible and Irreversible Decisions

Making decisions, even in areas you know relatively well, usually involves an element of uncertainty. Sometimes decisions can be made quickly, and uncertainty is acceptable or desirable. Other times, decisions are made slowly and deliberately to remove as much uncertainty as possible.

Once you are faced with a decision, the question becomes whether you should make it fast or slow.

Do you gather as much information as possible, knowing the process of gathering information slows you down and carries a cost? Or do you make it quickly with imperfect information?

Jeff Bezos, the founder of Amazon.com, considers decisions like doors. He asks himself if the decision is a one-way door or a two-way door. What's the difference?

Once you walk through a one-way door, you can't come back. It's irreversible. With a two-way door, on the other hand, you can walk through, look around, and easily come back to where you started.

In a shareholder letter, Bezos wrote^[1]:

Some decisions are consequential and irreversible or nearly irreversible – one-way doors – and these decisions must be made methodically, carefully, slowly, with great deliberation and consultation. If you walk through and don't like what you see on the other side, you can't get back to where you were before. We can call these Type 1 decisions. But most decisions aren't like that – they are changeable, reversible – they're two-way doors. If you've made a suboptimal Type 2 decision, you don't have to live with the consequences for that long. You can reopen the door and go back through. Type 2 decisions can and should be made quickly by high judgment individuals or small groups.

As organizations get larger, there seems to be a tendency to use the heavy-weight Type 1 decision-making process on most decisions, including many Type 2 decisions. The end result of this is slowness, unthoughtful risk aversion, failure to experiment sufficiently, and consequently diminished invention. We'll have to figure out how to fight that tendency.

Reversible to Irreversible

Decisions fall somewhere on the continuum from reversible to irreversible. You can tell where a decision lies on this spectrum by asking how much it would cost to undo. The higher the cost to undo, the more irreversible it is. The lower the cost, the more reversible it is.

Perhaps an example will help illustrate the point. After brushing your teeth this morning, you run to the store to grab some toothpaste. However, they are out of your usual brand. Since the decision is easily reversible, you quickly grab a package that looks decent and take it home. If the toothpaste is terrible, you can easily get another type tomorrow. Now consider an irreversible decision. Imagine you are the manager of an NBA team. You're thinking about trading one of your star players away. Once made, that decision can't (easily) be undone.

Once you learn to see decisions through the lens of reversible and irreversible, everything changes. It also changes how you make decisions.

Make reversible decisions as soon as possible and make irreversible decisions as late as possible.

When decisions are reversible, make them fast. Your biggest risk is dragging your feet and not making a decision. The cost to acquire additional information isn't worth the effort.

When decisions are irreversible, slow them down. The biggest risk is making the wrong decision. The cost to get the information we need to reduce uncertainty is worth the time and effort.

I used this heuristic to quit my job and start my first company. While some people saw this as a huge risk, I didn't. I realized that if the company failed, I would have learned a lot and could pretty easily return to my old job. It was a risk, but it wasn't as big as some thought. The future is unpredictable.

Sometimes you can handle the uncertainty or outcomes. Like trying a new restaurant after reading a review or hearing about it from someone at work. Other times, you want to remove as much uncertainty as possible. You wouldn't decide to marry someone after one amazing date, buy a car without test driving it, or put all your money into a stock you overheard someone talking about in line at the grocery store.

Avoiding Analysis Paralysis

Make reversible decisions as soon as possible. Make irreversible decisions as late as possible.

When I mention this rule to people, they ask: how do I know it's as late as possible?

Consider my rule of STOP, LOP, or KNOW. If you stop gathering useful information (STOP), you're about to lose an opportunity (LOP), or you know what to do (KNOW).

If you stop gathering useful information and there is no prospect of any on the horizon, make the decision. When you're in charge of operations at a three-letter agency, you make many hard decisions with imperfect information. Once you've talked to all the people with useful information, it's time to act. The problem is a lot of people don't act. They sit waiting for some magical piece of information that might or might not come that will make the decision clear. I call this unicorn information. We know it's out there, but we can never find it. You can't wait for the unicorn, you have to decide. The people that waited for the unicorn didn't last.

If you're about to lose a meaningful opportunity, make the decision. Recently a big real estate opportunity came across my desk. While not impossible to reverse, it would have been prohibitively costly. As with any decision that involves a lot of money — the biggest check I've ever written, I dove into the details wanting to understand everything. At first, there was no rush to make the decision. When interest rates started to rise, the deal got a lot more attractive. My partner called and asked if I was in because it was going forward with or without me. I had to decide, or I'd lose the opportunity.

If you know what to do, make the decision. When you're the boss, sometimes you have to let people go. While you can offer feedback and coach and hope things will change, sometimes you wake up and know what to do. Once you know it's best for both parties to move on, the biggest mistake is waiting.

Fast is not always Reckless.

Reversible decisions don't need to be made the same way as irreversible decisions.

Reversible decisions are not an excuse to act recklessly or be ill-informed, but rather an acknowledgement that imperfect decisions are ok.

Fast decisions are a competitive advantage. Warren Buffett has famously given a yes/no decision on acquisitions in less than 48 hours. Fast decisions are one advantage that start-ups have over incumbents.

A good plan, violently executed now, is better than a perfect plan next week.

General George Patton

Bezos considers 70% certainty as the cut-off point where it is appropriate to make a decision. That means acting once we have 70% of the required information, instead of waiting longer. Making a decision at 70% certainty and then quickly course-correcting is much more effective than waiting for 90% certainty.

More Information does not mean Better Outcomes.

In Blink: The Power of Thinking Without Thinking, Malcolm Gladwell explains why decision-making under uncertainty can be so effective. We usually assume that more

information leads to better decisions — if a doctor proposes additional tests, we tend to believe they will lead to a better outcome. Gladwell disagrees: “In fact, you need to know very little to find the underlying signature of a complex phenomenon. All you need is evidence of the ECG, blood pressure, fluid in the lungs, and an unstable angina. That’s a radical statement.”

In medicine, as in many areas, more information does not necessarily ensure improved outcomes. To illustrate this, Gladwell gives the example of a man arriving at a hospital with intermittent chest pains. His vital signs show no risk factors, yet his lifestyle does and he had heart surgery two years earlier. If a doctor looks at all the available information, it may seem that the man needs to be admitted to the hospital. But the additional factors, beyond the vital signs, are not important in the short term. In the long run, he is at serious risk of developing heart disease.

Gladwell writes:

... the role of those other factors is so small in determining what is happening to the man right now that an accurate diagnosis can be made without them. In fact, ... that extra information is more than useless. It's harmful. It confuses the issues. What screws up doctors when they are trying to predict heart attacks is that they take too much information into account.

Once you understand that reversible decisions are a great way to inject randomness, gather information, or even delegate to others, things change.

The biggest risk to irreversible decisions is deciding before you need to. The biggest risk to reversible ones is waiting until the last minute.

Make reversible decisions as soon as possible and make irreversible decisions as late as possible.

131. The Value of Probabilistic Thinking: Spies, Crime, and Lightning Strikes

Probabilistic thinking is essentially trying to estimate, using some tools of math and logic, the likelihood of any specific outcome coming to pass. It is one of the best tools we have to improve the accuracy of our decisions. In a world where each moment is determined by an infinitely complex set of factors, probabilistic thinking helps us identify the most likely outcomes. When we know these our decisions can be more precise and effective.

The Great Mental Models Volumes One and Two are out.

Learn more about [the project here](#).

Are you going to get hit by lightning or not?

Why we need the concept of probabilities at all is worth thinking about. Things either are or are not, right? We either *will* get hit by lightning today or we *won't*. The problem is, we just don't know until we live out the day, which doesn't help us at all when we make our decisions in the morning. The future is far from determined and we can better navigate it by understanding the likelihood of events that could impact us.

Our lack of perfect information about the world gives rise to all of probability theory, and its usefulness. We know now that the future is inherently unpredictable because not all variables can be known and even the smallest error imaginable in our data very quickly throws off our predictions. The best we can do is estimate the future by generating realistic, useful probabilities. So how do we do that?

Probability is everywhere, down to the very bones of the world. The probabilistic machinery in our minds—the cut-to-the-quick *heuristics* made so famous by the psychologists Daniel Kahneman and Amos Tversky—was evolved by the human species in a time before computers, factories, traffic, middle managers, and the stock market. It served us in a time when human life was about *survival*, and still serves us well in that capacity.

But what about today—a time when, for most of us, survival is not so much the issue? We want to *thrive*. We want to compete, and win. Mostly, we want to make good decisions in complex social systems that were not part of the world in which our brains evolved their (quite rational) heuristics.

For this, we need to consciously add in a needed layer of probability awareness. What is it and how can I use it to my advantage?

There are three important aspects of probability that we need to explain so you can integrate them into your thinking to get into the ballpark and improve your chances of catching the ball:

1. Bayesian thinking,
2. Fat-tailed curves
3. Asymmetries

Thomas Bayes and Bayesian thinking: Bayes was an English minister in the first half of the 18th century, whose most famous work, “An Essay Toward Solving a Problem in the Doctrine of Chances” was brought to the attention of the Royal Society by his friend Richard Price in 1763—two years after his death. The essay, the key to what we now know as Bayes’s Theorem, concerned how we should adjust probabilities when we encounter new data.

The core of Bayesian thinking (or Bayesian updating, as it can be called) is this: given that we have limited but useful information about the world, and are constantly encountering new information, we should probably take into account what we already know when we learn something new. As much of it as possible. Bayesian thinking allows us to use all relevant prior information in making decisions. Statisticians might call it a *base rate*, taking in outside information about past situations like the one you’re in.

Consider the headline “Violent Stabbings on the Rise.” Without Bayesian thinking, you might become genuinely afraid because your chances of being a victim of assault or murder is higher than it was a few months ago. But a Bayesian approach will have you putting this information into the context of what you already know about violent crime. You know that violent crime has been declining to its lowest rates in decades. Your city is safer now than it has been since this measurement started. Let’s say your chance of being a victim of a stabbing last year was one in 10,000, or 0.01%. The article states, with accuracy, that violent crime has doubled. It is now two in 10,000, or 0.02%. Is that worth being terribly worried about? The prior information here is key. When we factor it in, we realize that our safety has not really been compromised.

Conversely, if we look at the diabetes statistics in the United States, our application of prior knowledge would lead us to a different conclusion. Here, a Bayesian analysis indicates you should be concerned. In 1958, 0.93% of the population was diagnosed with diabetes. In 2015 it was 7.4%. When you look at the intervening years, the climb in diabetes diagnosis is steady, not a spike. So the prior relevant data, or priors, indicate a trend that is worrisome.

It is important to remember that priors themselves are probability estimates. For each bit of prior knowledge, you are not putting it in a binary structure, saying it is true or not. You’re assigning it a probability of being true. Therefore, you can’t let your priors get in the way of processing new knowledge. In Bayesian terms, this is called the likelihood ratio or the Bayes factor. Any new information you encounter that challenges a prior simply means that the probability of that prior being true may be reduced. Eventually, some priors are replaced completely. This is an ongoing cycle of challenging and validating what you believe you know. When making uncertain decisions, it’s nearly always a mistake not to ask: What are the relevant priors? What might I already know that I can use to better understand the reality of the situation?

Now we need to look at fat-tailed curves: Many of us are familiar with the bell curve, that nice, symmetrical wave that captures the relative frequency of so many things from height to exam scores. The bell curve is great because it’s easy to understand and easy to use. Its technical name is “normal distribution.” If we know we are in a bell curve situation, we can quickly identify our parameters and plan for the most likely outcomes.

Fat-tailed curves are different. Take a look.

At first glance they seem similar enough. Common outcomes cluster together, creating a wave. The difference is in the tails. In a bell curve the extremes are predictable. There can only be so much deviation from the mean. In a fat-tailed curve there is no real cap on extreme events.

The more extreme events that are possible, the longer the tails of the curve get. Any one extreme event is still unlikely, but the sheer number of options means that we can't rely on the most common outcomes as representing the average. The more extreme events that are possible, the higher the probability that one of them will occur. Crazy things are definitely going to happen, and we have no way of identifying when.

Think of it this way. In a bell curve type of situation, like displaying the distribution of height or weight in a human population, there are outliers on the spectrum of possibility, but the outliers have a fairly well defined scope. You'll never meet a man who is ten times the size of an average man. But in a curve with fat tails, like wealth, the central tendency does not work the same way. You may regularly meet people who are ten, 100, or 10,000 times wealthier than the average person. That is a very different type of world.

Let's re-approach the example of the risks of violence we discussed in relation to Bayesian thinking. Suppose you hear that you had a greater risk of slipping on the stairs and cracking your head open than being killed by a terrorist. The statistics, the priors, seem to back it up: 1,000 people slipped on the stairs and died last year in your country and only 500 died of terrorism. Should you be more worried about stairs or terror events?

Some use examples like these to prove that terror risk is low—since the recent past shows very few deaths, why worry?[1] The problem is in the fat tails: The risk of terror violence is more like wealth, while stair-slipping deaths are more like height and weight. In the next ten years, how many events are possible? How fat is the tail?

The important thing is not to sit down and imagine every possible scenario in the tail (by definition, it is impossible) but to deal with fat-tailed domains in the correct way: by positioning ourselves to survive or even benefit from the wildly unpredictable future, by being the only ones thinking correctly and planning for a world we don't fully understand. Asymmetries: Finally, you need to think about something we might call "metaprobability" — the probability that your probability estimates themselves are any good.

This massively misunderstood concept has to do with asymmetries. If you look at nicely polished stock pitches made by professional investors, nearly every time an idea is presented, the investor looks their audience in the eye and states they think they're going to achieve a rate of return of 20% to 40% per annum, if not higher. Yet *exceedingly* few of them ever attain that mark, and it's not because they don't have any winners. It's because they get so many so wrong. They consistently overestimate their confidence in their probabilistic estimates. (For reference, the general stock market has returned no more than 7% to 8% per annum in the United States over a long period, before fees.)

Another common asymmetry is people's ability to estimate the effect of traffic on travel time. How often do you leave "on time" and arrive 20% early? Almost never? How often do you leave "on time" and arrive 20% late? All the time? Exactly. Your estimation errors are asymmetric, skewing in a single direction. This is often the case with probabilistic decision-making.[2]

Far more probability estimates are wrong on the "over-optimistic" side than the "under-optimistic" side. You'll rarely read about an investor who aimed for 25% annual return rates who subsequently earned 40% over a long period of time. You can throw a dart at the Wall Street Journal and hit the names of lots of investors who aim for 25% per annum with each investment and end up closer to 10%.

The spy world

Successful spies are very good at probabilistic thinking. High-stakes survival situations tend to make us evaluate our environment with as little bias as possible.

When Vera Atkins was second in command of the French unit of the Special Operations Executive (SOE), a British intelligence organization reporting directly to Winston Churchill during World War II[3], she had to make hundreds of decisions by figuring out the probable accuracy of inherently unreliable information.

Atkins was responsible for the recruitment and deployment of British agents into occupied France. She had to decide who could do the job, and where the best sources of intelligence were. These were literal life-and-death decisions, and all were based in probabilistic thinking.

First, how do you choose a spy? Not everyone can go undercover in high-stress situations and make the contacts necessary to gather intelligence. The result of failure in France in WWII was not getting fired; it was death. What factors of personality and experience show that a person is right for the job? Even today, with advancements in psychology, interrogation, and polygraphs, it's still a judgment call.

For Vera Atkins in the 1940s, it was very much a process of assigning weight to the various factors and coming up with a probabilistic assessment of who had a decent chance of success. Who spoke French? Who had the confidence? Who was too tied to

family? Who had the problem-solving capabilities? From recruitment to deployment, her development of each spy was a series of continually updated, educated estimates. Getting an intelligence officer ready to go is only half the battle. Where do you send them? If your information was so great that you knew exactly where to go, you probably wouldn't need an intelligence mission. Choosing a target is another exercise in probabilistic thinking. You need to evaluate the reliability of the information you have and the networks you have set up. Intelligence is not evidence. There is no chain of command or guarantee of authenticity.

The stuff coming out of German-occupied France was at the level of grainy photographs, handwritten notes that passed through many hands on the way back to HQ, and unverifiable wireless messages sent quickly, sometimes sporadically, and with the operator under incredible stress. When deciding what to use, Atkins had to consider the relevancy, quality, and timeliness of the information she had.

She also had to make decisions based not only on what had happened, but what possibly could. Trying to prepare for every eventuality means that spies would never leave home, but they must somehow prepare for a good deal of the unexpected. After all, their jobs are often executed in highly volatile, dynamic environments. The women and men Atkins sent over to France worked in three primary occupations: organizers were responsible for recruiting locals, developing the network, and identifying sabotage targets; couriers moved information all around the country, connecting people and networks to coordinate activities; and wireless operators had to set up heavy communications equipment, disguise it, get information out of the country, and be ready to move at a moment's notice. All of these jobs were dangerous. The full scope of the threats was never completely identifiable. There were so many things that could go wrong, so many possibilities for discovery or betrayal, that it was impossible to plan for them all. The average life expectancy in France for one of Atkins' wireless operators was six weeks.

Finally, the numbers suggest an asymmetry in the estimation of the probability of success of each individual agent. Of the 400 agents that Atkins sent over to France, 100 were captured and killed. This is not meant to pass judgment on her skills or smarts.

Probabilistic thinking can only get you in the ballpark. It doesn't guarantee 100% success. There is no doubt that Atkins relied heavily on probabilistic thinking to guide her decisions in the challenging quest to disrupt German operations in France during World War II. It is hard to evaluate the success of an espionage career, because it is a job that comes with a lot of loss. Atkins was extremely successful in that her network conducted valuable sabotage to support the allied cause during the war, but the loss of life was significant.

Conclusion

Successfully thinking in shades of probability means roughly identifying what matters, coming up with a sense of the odds, doing a check on our assumptions, and then making a decision. We can act with a higher level of certainty in complex, unpredictable situations. We can never know the future with exact precision. Probabilistic thinking is an extremely useful tool to evaluate how the world will most likely look so that we can effectively strategize.

132. Inertia: The Force That Holds the Universe Together

Inertia is the force that holds the universe together. Literally. Without it, things would fall apart. It's also what keeps us locked in destructive habits, and resistant to change.

*

"If it were possible to flick a switch and turn off inertia, the universe would collapse in an instant to a clump of matter," write Peter and Neal Garneau in *In the Grip of the Distant Universe: The Science of Inertia*.

...death is the destination we all share. No one has ever escaped it. And that is as it should be, because death is very likely the single best invention of life. It's life's change agent; it clears out the old to make way for the new ... Your time is limited, so don't waste it living someone else's life.

Steve Jobs

Inertia is the force that holds the universe together. Literally. Without it, matter would lack the electric forces necessary to form its current arrangement. Inertia is counteracted by the heat and kinetic energy produced by moving particles. Subtract it and everything cools to -459.67 degrees Fahrenheit (absolute zero temperature). Yet we know so little about inertia and how to leverage it in our daily lives.

The Basics

The German astronomer Johannes Kepler (1571–1630) coined the word “inertia.” The etymology of the term is telling. Kepler obtained it from the Latin for “unskillfulness, ignorance; inactivity or idleness.” True to its origin, inertia keeps us in bed on a lazy Sunday morning (we need to apply activation energy to overcome this state).

Inertia refers to resistance to change — in particular, resistance to changes in motion. Inertia may manifest in physical objects or in the minds of people.

We learn the principle of inertia early on in life. We all know that it takes a force to get something moving, to change its direction, or to stop it.

Our intuitive sense of how inertia works enables us to exercise a degree of control over the world around us. Learning to drive offers further lessons. Without external physical forces, a car would keep moving in a straight line in the same direction. It takes a force (energy) to get a car moving and overcome the inertia that kept it still in a parking space. Changing

direction to round a corner or make a U-turn requires further energy. Inertia is why a car does not stop the moment the brakes are applied.

The heavier a vehicle is, the harder it is to overcome inertia and make it stop. A light bicycle stops with ease, while an eight-carriage passenger train needs a good mile to halt. Similarly, the faster we run, the longer it takes to stop. Running in a straight line is much easier than twisting through a crowded sidewalk, changing direction to dodge people. Any object that can be rotated, such as a wheel, has rotational inertia. This tells us how hard it is to change the object's speed around the axis. Rotational inertia depends on the mass of the object and its distribution relative to the axis.

Inertia is Newton's first law of motion, a fundamental principle of physics. Newton summarized it this way: "The vis insita, or innate force of matter, is a power of resisting by which every body, as much as in it lies, endeavors to preserve its present state, whether it be of rest or of moving uniformly forward in a straight line."

When developing his first law, Newton drew upon the work of Galileo Galilei. In a 1624 letter to Francesco Ingoli, Galileo outlined the principle of inertia:

I tell you that if natural bodies have it from Nature to be moved by any movement, this can only be a circular motion, nor is it possible that Nature has given to any of its integral bodies a propensity to be moved by straight motion. I have many confirmations of this proposition, but for the present one alone suffices, which is this.

I suppose the parts of the universe to be in the best arrangement so that none is out of its place, which is to say that Nature and God have perfectly arranged their structure...

Therefore, if the parts of the world are well ordered, the straight motion is superfluous and not natural, and they can only have it when some body is forcibly removed from its natural place, to which it would then return to a straight line.

In 1786, Immanuel Kant elaborated further: "All change of matter has an external cause. (Every body remains in its state of rest or motion in the same direction and with the same velocity, if not compelled by an external cause to forsake this state.) ... This mechanical law can only be called the law of inertia (lex inertiae)...."

Now that we understand the principle, let's look at some of the ways we can understand it better and apply it to our advantage.

Decision Making and Cognitive Inertia

We all experience cognitive inertia: the tendency to stick to existing ideas, beliefs, and habits even when they no longer serve us well. Few people are truly able to revise their opinions in light of disconfirmatory information. Instead, we succumb to confirmation bias and seek out verification of existing beliefs. It's much easier to keep thinking what we've always been thinking than to reflect on the chance that we might be wrong and update our views. It takes work to overcome cognitive dissonance, just as it takes effort to stop a car or change its direction.

When the environment changes, clinging to old beliefs can be harmful or even fatal.

Whether we fail to perceive the changes or fail to respond to them, the result is the same.

Even when it's obvious to others that we must change, it's not obvious to us. It's much easier to see something when you're not directly involved. If I ask you how fast you're moving right now, you'd likely say zero, but you're moving 18,000 miles an hour around the sun. Perspective is everything, and the perspective that matters is the one that most closely lines up with reality.

Sometimes you make up your mind about something without knowing why, and your decision persists by the power of inertia. Every year it gets harder to change.

Milan Kundera, *The Unbearable Lightness of Being*

Cognitive inertia is the reason that changing our habits can be difficult. The default is always the path of least resistance, which is easy to accept and harder to question. Consider your bank, for example. Perhaps you know that there are better options at other banks. Or you have had issues with your bank that took ages to get sorted. Yet very few people actually change their banks, and many of us stick with the account we first opened. After all, moving away from the status quo would require a lot of effort: researching alternatives, transferring balances, closing accounts, etc. And what if something goes wrong? Sounds risky. The switching costs are high, so we stick to the status quo. Sometimes inertia helps us. After all, questioning everything would be exhausting. But in many cases, it is worthwhile to overcome inertia and set something in motion, or change direction, or halt it.

The important thing about inertia is that it is only the initial push that is difficult. After that, progress tends to be smoother. Ernest Hemingway had a trick for overcoming inertia in his writing. Knowing that getting started was always the hardest part, he chose to finish work each day at a point where he had momentum (rather than when he ran out of ideas). The next day, he could pick up from there. In *A Moveable Feast*, Hemingway explains: *I always worked until I had something done and I always stopped when I knew what was going to happen next. That way I could be sure of going on the next day.*

Later on in the book, he describes another method, which was to write just one sentence: *Do not worry. You have always written before and you will write now. All you have to do is write one true sentence. Write the truest sentence that you know. So, finally I would write one true sentence and go on from there. It was easy then because there was always one true sentence that I knew or had seen or had heard someone say. If I started to write elaborately, or like someone introducing or presenting something, I found that I could cut that scrollwork or ornament out and throw it away and start with the first true simple declarative sentence I had written.*

We can learn a lot from Hemingway's approach to tackling inertia and apply it in areas beyond writing. As with physics, the momentum from getting started can carry us a long way. We just need to muster the required activation energy and get going.

Status Quo Bias: "When in Doubt, Do Nothing"

Cognitive inertia also manifests in the form of status quo bias. When making decisions, we are rarely rational. Faced with competing options and information, we often opt for the default because it's easy. Doing something other than what we're already doing requires mental energy that we would rather preserve. In many areas, this helps us avoid decision fatigue.

Many of us eat the same meals most of the time, wear similar outfits, and follow routines. This tendency usually serves us well. But the status quo is not necessarily the optimum solution. Indeed, it may be outright harmful or at least unhelpful if something has changed in the environment or we want to optimize our use of time.

The great enemy of any attempt to change men's habits is inertia. Civilization is limited by inertia.

Edward L. Bernays, *Propaganda*

In a paper entitled "If you like it, does it matter if it's real?" Felipe De Brigard^[1] offers a powerful illustration of status quo bias. One of the best-known thought experiments concerns Robert Nozick's "experience machine." Nozick asked us to imagine that scientists have created a virtual reality machine capable of simulating any pleasurable experience. We are offered the opportunity to plug ourselves in and live out the rest of our lives in permanent, but fake enjoyment. The experience machine would later inspire the *Matrix* film series. Presented with the thought experiment, most people balk and claim they would prefer reality. But what if we flip the narrative? De Brigard believed that we are

opposed to the experience machine because it contradicts the status quo, the life we are accustomed to.

In an experiment, he asked participants to imagine themselves woken by the doorbell on a Saturday morning. A man in black, introducing himself as Mr. Smith, is at the door. He claims to have vital information. Mr. Smith explains that there has been an error and you are in fact connected to an experience machine. Everything you have lived through so far has been a simulation. He offers a choice: stay plugged in, or return to an unknown real life. Unsurprisingly, far fewer people wished to return to reality in the latter situation than wished to remain in it in the former. The aversive element is not the experience machine itself, but the departure from the status quo it represents.

Conclusion

Inertia is a pervasive, problematic force. It's the pull that keeps us clinging to old ways and prevents us from trying new things. But as we have seen, it is also a necessary one.

Without it, the universe would collapse. Inertia is what enables us to maintain patterns of functioning, maintain relationships, and get through the day without questioning everything. We can overcome inertia much like Hemingway did — by recognizing its influence and taking the necessary steps to create that all-important initial momentum.

133. Deductive vs Inductive Reasoning: Make Smarter Arguments, Better Decisions, and Stronger Conclusions

You can't prove truth, but using deductive and inductive reasoning, you can get close. Learn the difference between the two types of reasoning and how to use them when evaluating facts and arguments.

In this article we'll cover:

- What Makes Something True?
- Reasoning by Induction
- Reasoning by Deduction
- The History of Reasoning

Ok, let's dig in and see what we can learn.

What Makes Something True?

As odd as it sounds, in science, law, and many other fields, there is no such thing as proof — there are only conclusions drawn from facts and observations. Scientists cannot prove a hypothesis, but they can collect evidence that points to its being true. Lawyers cannot prove that something happened (or didn't), but they can provide evidence that seems irrefutable.

The question of what makes something true is more relevant than ever in this era of alternative facts and fake news. This article explores truth — what it means and how we establish it. We'll dive into inductive and deductive reasoning as well as a bit of history.

"Contrariwise," continued Tweedledee, "if it was so, it might be; and if it were so, it would be; but as it isn't, it ain't. That's logic."

— Lewis Carroll, *Through the Looking-Glass*

The essence of reasoning is a search for truth. Yet truth isn't always as simple as we'd like to believe it is.

For as far back as we can imagine, philosophers have debated whether absolute truth exists. Although we're still waiting for an answer, this doesn't have to stop us from improving how we think by understanding a little more.

In general, we can consider something to be true if the available evidence seems to verify it. The more evidence we have, the stronger our conclusion can be. When it comes to samples, size matters. As my friend Peter Kaufman says:

What are the three largest, most relevant sample sizes for identifying universal principles? Bucket number one is inorganic systems, which are 13.7 billion years in size. It's all the laws of math and physics, the entire physical universe. Bucket number two is organic systems, 3.5 billion years of biology on Earth. And bucket number three is human history....

In some areas, it is necessary to accept that truth is subjective. For example, ethicists accept that it is difficult to establish absolute truths concerning whether something is right or wrong, as standards change over time and vary around the world. When it comes to reasoning, a correctly phrased statement can be considered to have objective truth. Some statements have an objective truth that we cannot ascertain at present. For example, we do not have proof for the existence or non-existence of aliens, although proof does exist somewhere.

Deductive and inductive reasoning are both based on evidence.

Several types of evidence are used in reasoning to point to a truth:

- Direct or experimental evidence — This relies on observations and experiments, which should be repeatable with consistent results.
- Anecdotal or circumstantial evidence — Overreliance on anecdotal evidence can be a logical fallacy because it is based on the assumption that two coexisting factors are linked even though alternative explanations have not been explored. The main use of anecdotal evidence is for forming hypotheses which can then be tested with experimental evidence.
- Argumentative evidence — We sometimes draw conclusions based on facts. However, this evidence is unreliable when the facts are not directly testing a hypothesis. For example, seeing a light in the sky and concluding that it is an alien aircraft would be argumentative evidence.
- Testimonial evidence — When an individual presents an opinion, it is testimonial evidence. Once again, this is unreliable, as people may be biased and there may not be any direct evidence to support their testimony.

“The weight of evidence for an extraordinary claim must be proportioned to its strangeness.”

— Laplace, *Théorie analytique des probabilités* (1812)

Reasoning by Induction

The fictional character Sherlock Holmes is a master of induction. He is a careful observer who processes what he sees to reach the most likely conclusion in the given set of circumstances. Although he pretends that his knowledge is of the black-or-white variety, it often isn't. It is true induction, coming up with the strongest possible explanation for the phenomena he observes.

Consider his description of how, upon first meeting Watson, he reasoned that Watson had just come from Afghanistan:

“Observation with me is second nature. You appeared to be surprised when I told you, on our first meeting, that you had come from Afghanistan.”

“You were told, no doubt.”

“Nothing of the sort. I knew you came from Afghanistan. From long habit the train of thoughts ran so swiftly through my mind, that I arrived at the conclusion without being conscious of intermediate steps. There were such steps, however. The train of reasoning ran, ‘Here is a gentleman of a medical type, but with the air of a military man. Clearly an army doctor, then. He has just come from the tropics, for his face is dark, and that is not the natural tint of his skin, for his wrists are fair. He has undergone hardship and sickness, as his haggard face says clearly. His left arm has been injured. He holds it in a stiff and unnatural manner. Where in the tropics could an English army doctor have seen much hardship and got his arm wounded? Clearly in Afghanistan.’ The whole train of thought did not occupy a second. I then remarked that you came from Afghanistan, and you were astonished.”

(From Sir Arthur Conan Doyle's A Study in Scarlet)

Inductive reasoning involves drawing conclusions from facts, using logic. We draw these kinds of conclusions all the time. If someone we know to have good literary taste recommends a book, we may assume that means we will enjoy the book.

Induction can be strong or weak. If an inductive argument is strong, the truth of the premise would mean the conclusion is likely. If an inductive argument is weak, the logic connecting the premise and conclusion is incorrect.

There are several key types of inductive reasoning:

- Generalized — Draws a conclusion from a generalization. For example, “All the swans I have seen are white; therefore, all swans are probably white.”
- Statistical — Draws a conclusion based on statistics. For example, “95 percent of swans are white” (an arbitrary figure, of course); “therefore, a randomly selected swan will probably be white.”
- Sample — Draws a conclusion about one group based on a different, sample group. For example, “There are ten swans in this pond and all are white; therefore, the swans in my neighbor’s pond are probably also white.”
- Analogous — Draws a conclusion based on shared properties of two groups. For example, “All Aylesbury ducks are white. Swans are similar to Aylesbury ducks. Therefore, all swans are probably white.”
- Predictive — Draws a conclusion based on a prediction made using a past sample. For example, “I visited this pond last year and all the swans were white. Therefore, when I visit again, all the swans will probably be white.”
- Causal inference — Draws a conclusion based on a causal connection. For example, “All the swans in this pond are white. I just saw a white bird in the pond. The bird was probably a swan.”

The entire legal system is designed to be based on sound reasoning, which in turn must be based on evidence. Lawyers often use inductive reasoning to draw a relationship between facts for which they have evidence and a conclusion.

The initial facts are often based on generalizations and statistics, with the implication that a conclusion is most likely to be true, even if that is not certain. For that reason, evidence can rarely be considered certain. For example, a fingerprint taken from a crime scene would be said to be “consistent with a suspect’s prints” rather than being an exact match. Implicit in that statement is the assertion that it is statistically unlikely that the prints are not the suspect’s.

Inductive reasoning also involves Bayesian updating. A conclusion can seem to be true at one point until further evidence emerges and a hypothesis must be adjusted. Bayesian updating is a technique used to modify the probability of a hypothesis’s being true as new evidence is supplied. When inductive reasoning is used in legal situations, Bayesian thinking is used to update the likelihood of a defendant’s being guilty beyond a reasonable doubt as evidence is collected. If we imagine a simplified, hypothetical criminal case, we can picture the utility of Bayesian inference combined with inductive reasoning.

Let’s say someone is murdered in a house where five other adults were present at the time. One of them is the primary suspect, and there is no evidence of anyone else entering the house. The initial probability of the prime suspect’s having committed the murder is 20 percent. Other evidence will then adjust that probability. If the four other people testify that they saw the suspect committing the murder, the suspect’s prints are on the murder weapon, and traces of the victim’s blood were found on the suspect’s clothes, jurors may consider the probability of that person’s guilt to be close enough to 100 percent to convict. Reality is more complex than this, of course. The conclusion is never certain, only highly probable.

One key distinction between deductive and inductive reasoning is that the latter accepts that a conclusion is uncertain and may change in the future. A conclusion is either strong or weak, not right or wrong. We tend to use this type of reasoning in everyday life, drawing conclusions from experiences and then updating our beliefs.

[quote]A conclusion is either strong or weak, not right or wrong.[/quote]

Everyday inductive reasoning is not always correct, but it is often useful. For example, superstitious beliefs often originate from inductive reasoning. If an athlete performed well on a day when they wore their socks inside out, they may conclude that the inside-out socks brought them luck. If future successes happen when they again wear their socks inside out, the belief may strengthen. Should that not be the case, they may update their belief and recognize that it is incorrect.

Another example (let's set aside the question of whether turkeys can reason): A farmer feeds a turkey every day, so the turkey assumes that the farmer cares for its wellbeing. Only when Thanksgiving rolls around does that assumption prove incorrect.

The issue with overusing inductive reasoning is that cognitive shortcuts and biases can warp the conclusions we draw. Our world is not always as predictable as inductive reasoning suggests, and we may selectively draw upon past experiences to confirm a belief. Someone who reasons inductively that they have bad luck may recall only unlucky experiences to support that hypothesis and ignore instances of good luck.

In *The 12 Secrets of Persuasive Argument*, the authors write:

In inductive arguments, focus on the inference. When a conclusion relies upon an inference and contains new information not found in the premises, the reasoning is inductive. For example, if premises were established that the defendant slurred his words, stumbled as he walked, and smelled of alcohol, you might reasonably infer the conclusion that the defendant was drunk. This is inductive reasoning. In an inductive argument the conclusion is, at best, probable. The conclusion is not always true when the premises are true. The probability of the conclusion depends on the strength of the inference from the premises. Thus, when dealing with inductive reasoning, pay special attention to the inductive leap or inference, by which the conclusion follows the premises.

... There are several popular misconceptions about inductive and deductive reasoning. When Sherlock Holmes made his remarkable "deductions" based on observations of various facts, he was usually engaging in inductive, not deductive, reasoning.

In *Inductive Reasoning*, Aiden Feeney and Evan Heit write:

...inductive reasoning ... corresponds to everyday reasoning. On a daily basis we draw inferences such as how a person will probably act, what the weather will probably be like, and how a meal will probably taste, and these are typical inductive inferences.

[...]

[I]t is a multifaceted cognitive activity. It can be studied by asking young children simple questions involving cartoon pictures, or it can be studied by giving adults a variety of complex verbal arguments and asking them to make probability judgments.

[...]

[I]nduction is related to, and it could be argued is central to, a number of other cognitive activities, including categorization, similarity judgment, probability judgment, and decision making. For example, much of the study of induction has been concerned with category-based induction, such as inferring that your next door neighbor sleeps on the basis that your neighbor is a human animal, even if you have never seen your neighbor sleeping. "A very great deal more truth can become known than can be proven."

— Richard Feynman

Reasoning by Deduction

Deduction begins with a broad truth (the major premise), such as the statement that all men are mortal. This is followed by the minor premise, a more specific statement, such as that Socrates is a man. A conclusion follows: Socrates is mortal. If the major premise is true and the minor premise is true the conclusion cannot be false.

Deductive reasoning is black and white; a conclusion is either true or false and cannot be partly true or partly false. We decide whether a deductive statement is true by assessing

the strength of the link between the premises and the conclusion. If all men are mortal and Socrates is a man, there is no way he can not be mortal, for example. There are no situations in which the premise is not true, so the conclusion is true.

In science, deduction is used to reach conclusions believed to be true. A hypothesis is formed; then evidence is collected to support it. If observations support its truth, the hypothesis is confirmed. Statements are structured in the form of “if A equals B, and C is A, then C is B.” If A does not equal B, then C will not equal B. Science also involves inductive reasoning when broad conclusions are drawn from specific observations; data leads to conclusions. If the data shows a tangible pattern, it will support a hypothesis.

For example, having seen ten white swans, we could use inductive reasoning to conclude that all swans are white. This hypothesis is easier to disprove than to prove, and the premises are not necessarily true, but they are true given the existing evidence and given that researchers cannot find a situation in which it is not true. By combining both types of reasoning, science moves closer to the truth. In general, the more outlandish a claim is, the stronger the evidence supporting it must be.

We should be wary of deductive reasoning that appears to make sense without pointing to a truth. Someone could say “A dog has four paws. My pet has four paws. Therefore, my pet is a dog.” The conclusion sounds logical but isn’t, because the initial premise is too specific.

The History of Reasoning

The discussion of reasoning and what constitutes truth dates back to Plato and Aristotle. Plato (429–347 BC) believed that all things are divided into the visible and the intelligible. Intelligible things can be known through deduction (with observation being of secondary importance to reasoning) and are true knowledge.

Aristotle took an inductive approach, emphasizing the need for observations to support knowledge. He believed that we can reason only from discernable phenomena. From there, we use logic to infer causes.

Debate about reasoning remained much the same until the time of Isaac Newton.

Newton’s innovative work was based on observations, but also on concepts that could not be explained by a physical cause (such as gravity). In his *Principia*, Newton outlined four rules for reasoning in the scientific method:

1. “We are to admit no more causes of natural things than such as are both true and sufficient to explain their appearances.” (We refer to this rule as Occam’s Razor.)
2. “Therefore, to the same natural effects we must, as far as possible, assign the same causes.”
3. “The qualities of bodies, which admit neither intensification nor remission of degrees, and which are found to belong to all bodies within the reach of our experiments, are to be esteemed the universal qualities of all bodies whatsoever.”
4. “In experimental philosophy, we are to look upon propositions collected by general induction from phenomena as accurately or very nearly true, notwithstanding any contrary hypotheses that may be imagined, ’till such time as other phenomena occur, by which they may either be made more accurate, or liable to exceptions.”

In 1843, philosopher John Stuart Mill published *A System of Logic*, which further refined our understanding of reasoning. Mill believed that science should be based on a search for regularities among events. If a regularity is consistent, it can be considered a law. Mill described five methods for identifying causes by noting regularities. These methods are still used today:

- Direct method of agreement — If two instances of a phenomenon have a single circumstance in common, the circumstance is the cause or effect.

- Method of difference — If a phenomenon occurs in one experiment and does not occur in another, and the experiments are the same except for one factor, that is the cause, part of the cause, or the effect.
- Joint method of agreement and difference — If two instances of a phenomenon have one circumstance in common, and two instances in which it does not occur have nothing in common except the absence of that circumstance, then that circumstance is the cause, part of the cause, or the effect.
- Method of residue — When you subtract any part of a phenomenon known to be caused by a certain antecedent, the remaining residue of the phenomenon is the effect of the remaining antecedents.
- Method of concomitant variations — If a phenomenon varies when another phenomenon varies in a particular way, the two are connected.

Karl Popper was the next theorist to make a serious contribution to the study of reasoning. Popper is well known for his focus on disconfirming evidence and disproving hypotheses. Beginning with a hypothesis, we use deductive reasoning to make predictions. A hypothesis will be based on a theory — a set of independent and dependent statements. If the predictions are true, the theory is true, and vice versa. Popper's theory of falsification (disproving something) is based on the idea that we cannot prove a hypothesis; we can only show that certain predictions are false. This process requires vigorous testing to identify any anomalies, and Popper does not accept theories that cannot be physically tested. Any phenomenon not present in tests cannot be the foundation of a theory, according to Popper. The phenomenon must also be consistent and reproducible. Popper's theories acknowledge that theories that are accepted at one time are likely to later be disproved. Science is always changing as more hypotheses are modified or disproved and we inch closer to the truth.

Conclusion

In *How to Deliver a TED Talk*, Jeremy Donovan writes:

No discussion of logic is complete without a refresher course in the difference between inductive and deductive reasoning. By its strictest definition, inductive reasoning proves a general principle—your idea worth spreading—by highlighting a group of specific events, trends, or observations. In contrast, deductive reasoning builds up to a specific principle—again, your idea worth spreading—through a chain of increasingly narrow statements.

Logic is an incredibly important skill, and because we use it so often in everyday life, we benefit by clarifying the methods we use to draw conclusions. Knowing what makes an argument sound is valuable for making decisions and understanding how the world works. It helps us to spot people who are deliberately misleading us through unsound arguments. Understanding reasoning is also helpful for avoiding fallacies and for negotiating.

135. The Disproportional Power of Anecdotes

Anecdotes tend to not be statistically significant, but their added emotional significance leads us to place additional weight on them.

Humans, it seems, have an innate tendency to overgeneralize from small samples. How many times have you been caught in an argument where the only proof offered is anecdotal? Perhaps your co-worker saw this bratty kid make a mess in the grocery store while the parents appeared to do nothing. “They just let that child pull things off the shelves and create havoc! My parents would never have allowed that. Parents are so permissive now.” Hmm. Is it true that most parents commonly allow young children to cause trouble in public? It would be a mistake to assume so based on the evidence presented, but a lot of us would go with it anyway. Your co-worker did.

Our propensity to confuse the “now” with “what always is,” as if the immediate world before our eyes consistently represents the entire universe, leads us to bad conclusions and bad decisions. We don’t bother asking questions and verifying validity. So we make mistakes and allow ourselves to be easily manipulated.

Political polling is a good example. It’s actually really hard to design and conduct a good poll. Matthew Mendelsohn and Jason Brent, in their article “Understanding Polling Methodology,” say:

Public opinion cannot be understood by using only a single question asked at a single moment. It is necessary to measure public opinion along several different dimensions, to review results based on a variety of different wordings, and to verify findings on the basis of repetition. Any one result is filled with potential error and represents one possible estimation of the state of public opinion.

This makes sense. But it’s amazing how often we forget.

We see a headline screaming out about the state of affairs and we dive right in, instant believers, without pausing to question the validity of the methodology. How many people did they sample? How did they select them? Most polling aims for random sampling, but there is pre-selection at work immediately, depending on the medium the pollsters use to reach people.

Truly random samples of people are hard to come by. In order to poll people, you have to be able to reach them. The more complicated this is, the more expensive the poll becomes, which acts as a deterrent to thoroughness. The internet can offer high accessibility for a relatively low cost, but it’s a lot harder to verify the integrity of the demographics. And if you go the telephone route, as a lot of polling does, are you already distorting the true randomness of your sample size? Are the people who answer “unknown” numbers already different from those who ignore them?

Polls are meant to generalize larger patterns of behavior based on small samples. You need to put a lot of effort in to make sure that sample is truly representative of the population you are trying to generalize about. Otherwise, erroneous information is presented as truth.

Why does this matter?

It matters because generalization is a widespread human bias, which means a lot of our understanding of the world actually is based on extrapolations made from relatively small sample sizes. Consequently, our individual behavior is shaped by potentially incomplete or inadequate facts that we use to make the decisions that are meant to lead us to success. This bias also shapes a fair degree of public policy and government legislation. We don’t want people who make decisions that affect millions to be dependent on captivating bullshit. (A further concern is that once you are invested, other biases kick in).

Some really smart people are perpetual victims of the problem.

Joseph Henrich, Steven J. Heine, and Ara Norenzayan wrote an article called "The weirdest people in the world?" It's about how many scientific psychology studies use college students who are predominantly Western, Educated, Industrialized, Rich, and Democratic (WEIRD), and then draw conclusions about the entire human race from these outliers. They reviewed scientific literature from domains such as "visual perception, fairness, cooperation, spatial reasoning, categorization and inferential induction, moral reasoning, and the heritability of IQ. The findings suggest that members of WEIRD societies, including young children, are among the least representative populations one could find for generalizing about humans."

Uh-oh. This is a double whammy. "It's not merely that researchers frequently make generalizations from a narrow subpopulation. The concern is that this particular subpopulation is highly unrepresentative of the species."

This is why it can be dangerous to make major life decisions based on small samples, like anecdotes or a one-off experience. The small sample may be an outlier in the greater range of possibilities. You could be correcting for a problem that doesn't exist or investing in an opportunity that isn't there.

This tendency of mistaken extrapolation from small samples can have profound consequences.

Are you a fan of the San Francisco 49ers? They exist, in part, because of our tendency to over-generalize. In the 19th century in Western America and Canada, a few findings of gold along some creek beds led to a massive rush as entire populations flocked to these regions in the hope of getting rich. San Francisco grew from 200 residents in 1846 to about 36,000 only six years later. The gold rush provided enormous impetus toward California becoming a state, and the corresponding infrastructure developments touched off momentum that long outlasted the mining of gold.

But for most of the actual rushers, those hoping for gold based on the anecdotes that floated east, there wasn't much to show for their decision to head west. The *Canadian Encyclopedia* states, "If the nearly 29 million (figure unadjusted) in gold that was recovered during the heady years of 1897 to 1899 [in the Klondike] was divided equally among all those who participated in the gold rush, the amount would fall far short of the total they had invested in time and money."

How did this happen? Because those miners took anecdotes as being representative of a broader reality. Quite literally, they learned mining from rumor, and didn't develop any real knowledge. Most people fought for claims along the creeks, where easy gold had been discovered, while rejecting the bench claims on the hillsides above, which often had just as much gold.

You may be thinking that these men must have been desperate if they packed themselves up, heading into unknown territory, facing multiple dangers along the way, to chase a dream of easy money. But most of us aren't that different. How many times have you invested in a "hot stock" on a tip from one person, only to have the company go under within a year? Ultimately, the smaller the sample size, the greater role the factors of chance play in determining an outcome.

If you want to limit the capriciousness of chance in your quest for success, increase your sample size when making decisions. You need enough information to be able to plot the range of possibilities, identify the outliers, and define the average.

So next time you hear the words "the polls say," "studies show," or "you should buy this," ask questions before you take action. Think about the population that is actually being represented before you start modifying your understanding. Accept the limits of small sample sizes from large populations. And don't give power to anecdotes.

136. Winner Takes it All: How Markets Favor the Few at the Expense of the Many

Markets tend to favor unequal distributions of market share and profits, with a few leaders emerging in any industry. Winner-take-all markets are hard to disrupt and suppress the entry of new players by locking in market share for leading players.

In almost any market, crowds of competitors fight for business within their niche. But over time, with few exceptions, a small number of companies come to dominate the industry. These are the names we all know. The logos we see every day. The brands which shape the world with every decision they make. Even those which are not household names have a great influence on our lives. Operating behind the scenes, they quietly grow more powerful each year, often sowing the seeds of their own destruction in the process.

A winner-take-all market doesn't mean there is only one company in the market. Rather, when we say a winner takes all, what we mean is that a single company receives the majority of available profits. A few others have at best a modest share. The rest fight over a miniscule remnant, and tend not to survive long.

In a winner-take-all market, the winners have tremendous power to dictate outcomes. Winner-take-all markets occur in many different areas. We can apply the concept to all situations which involve unequal distributions.

Unequal Distribution

As a general rule, resources are never distributed evenly among people. In almost every situation, a small number of people or organizations are the winners.

Most of the books sold each year are written by a handful of authors. Most internet traffic is to a few websites. The top 100 websites get more traffic than ranks 100-999 combined (welcome to power laws). Most citations in any field refer to the same few papers and researchers. Most clicks on Google searches are on the first result. Each of these is an instance of a winner-take-all market.

Wealth is a prime example of this type of market. The Pareto Principle states that in a given nation, 20% of the people own 80% of the wealth (the actual figures are 15% and 85%.) However, the Pareto Principle goes deeper than that. We can look at the richest 20%, then calculate the wealth of the richest 20% of that group. Once again, the Pareto principle applies. So roughly 4% own 64% of the wealth. Keep repeating that calculation and we end up with about 9 people. By some estimates, this tiny group has as much as wealth as the poorest half of the world.

“With limited time or opportunity to experiment, we intentionally narrow our choices to those at the top.”

— Seth Godin

The Perks of Being the Best

There are tremendous benefits to being the best in any particular area. Top performers might be only slightly more skilled than the people one level below them, yet they receive an exponential payoff. A small difference in relative performance—an athlete who can run 100 meters a few microseconds faster, a leader who can make better decisions, an opera singer who can go a little higher—can mean the difference between a lucrative career and relative obscurity. The people at the tops of their fields get it all. They are the winners in that particular market. And once someone is regarded as the best, they tend to retain that status. It takes a monumental effort for a newcomer to rise to such a position. Every day new people do make it to the top, but it's a lot easier to stay there than to get there.

Top performers don't just earn the most. They also tend to receive the majority of media coverage and win most awards. They have the most leverage when it comes to choosing their work. These benefits are exponential, following a power law distribution. A silver

medalist might get 10 times the benefits the bronze medalist does. But the gold medalist will receive 10 times the benefits of the silver. If a company is risking millions over a lawsuit, they will want the best possible lawyer no matter the cost. And a surgeon who is 10% better than average can charge more than 10% higher fees. When someone or something is the best, we hear about it. The winners take all the attention. It's one reason why the careers of Nobel Prize winners tend to go downhill after receiving the award. It becomes too lucrative for them to devote their time to the media, giving talks or writing books. Producing more original research falls by the wayside.

Leverage

One reason the best are rewarded more now than ever is leverage. Up until recently, if you were a nanosecond faster than someone else, there was no real advantage. Now there is. Small differences in performance translate into large differences in real-world benefits. A gold medallist in the Olympics, even one that wins by a nanosecond, is disproportionately rewarded for a very small edge.

Now we all live in a world of leverage, through capital, technology, and productivity. Leveraged workers can outperform unleveraged ones by orders of magnitude. When you're leveraged, judgment becomes far more important. That small difference in ability can be put to better use. Software engineers can create billions of dollars of value through code. Ten coders working 10 times harder but slightly less effective in their thinking will have nothing to show for it. Just as with winner-take-all markets, the inputs don't match the outputs.

Feedback Loops

Economist Sherwin Rosen looked at unequal distribution in *The Economics of Superstars*. Rosen found that the demand for classical music and live comedy is high and continues to grow. Yet each area only employs about two hundred full-time performers. These top-performing comedians and musicians take most of the market. Meanwhile, thousands of others struggle for any recognition. Performers regarded as second best within a field earn considerably less than the top performers, even though the average person cannot discern any difference.

In *Success and Luck*, Robert H. Frank explains the self-perpetuating nature of winner take all markets:

Is the Mona Lisa special? Is Kim Kardashian? They're both famous, but sometimes things are famous just for being famous. Although we often try to explain their success by scrutinising their objective qualities, they are in fact often no more special than many of their less renowned counterparts...Success often results from positive feedback loops that amplify tiny initial variations into enormous differences in final outcomes.

Winner-take-all markets are increasingly dictated by feedback loops. Feedback loops develop when the output becomes the input. Consider books. More people will buy a best-selling book because it's a best-selling book. More people will listen to a song that tops charts. More people will go to see an Oscar winning film. These feedback loops serve to magnify initial luck or manipulation. Some writers will purchase thousands of copies of their own book to push it onto best seller lists. Once it makes it onto the list, the feedback loop will begin and possibly keep it there longer than it merits.¹

It's hard to establish what sets off these feedback loops. In many cases, the answer is simple: luck. Although many people and organizations create narratives to explain their achievements, luck plays a large role. This is a combination of hindsight bias and the narrative fallacy. In retrospect, becoming the winner in the market seems inevitable. In truth, luck plays a substantial role in the creation of winner-take-all markets. A combination of timing, location and connections serves to create winners. Their status is never inevitable, no matter what they might tell those who ask.

In some cases, governments deliberately strive to create positive feedback loops. Drug patents are one example. These create a powerful incentive for companies to invest in

research and development. Releasing a new, copyrighted drug is a lucrative enterprise. As the only company in that particular market, a company can set the price to whatever it wishes. Until the patent runs out, that company is the winner. This is exactly how the market plays out. In 2016, the highest grossing drug company earned \$71 billion. The three runners up each earned around \$50 billion. From there on, the other drug companies have a comparatively small share of the market.

Profit enables companies to invest in more research and development, pay employees more, and invest in their communities. A positive feedback loop forms. Talented researchers join successful teams. They gather valuable data. Developing new drugs becomes easier. Drug companies gain greater and greater market power over time. A few winners end up with almost total control. They become the names we trust and hold their position, absorbing any risks or scandals. New effective drugs benefit society on the whole, improving our well-being. This winner-take-all market has its upsides. Issues emerge when patent holders set prices above the means of the people who need the drugs most.

Once the patent runs out on a drug (generally after 12 years) any other firm can produce an identical product. Prices soon fall as other companies enter the market. The feedback loop breaks, and the winner no longer takes all. Even so, the former winner will retain a large share of the market. People tend to be unwilling to switch to a new brand of drug, even if it has the same effects.

Ironically, winner-take-all markets tend to perpetuate themselves by attracting more losers. When we look at founders in Silicon Valley or actors in LA, we don't see the failures. Survivorship bias means we only see those who succeed. Attracted by the thought of winning, growing numbers of people flock to try their luck in the market. Most fail, overconfident and misled. The rewards become even more concentrated. More people are attracted and the cycle continues.

DeBeers Diamonds

In the market for diamonds, there is one main winner: DeBeers. This international corporation controls most of the global diamond market, including mining, trading and retail. For around a century, DeBeers had a complete monopoly. Diamonds are a scarce Veblen good with minimal practical use. The value depends on our perception.

Prior to the late 19th century, the global production of diamonds totaled a couple of pounds a year. Demand barely existed, so no one had much interest in supplying it. However, the discovery of several large mines increased production from pounds to tons. Those who stood to profit recognized that diamonds have no intrinsic value. They needed to create a perception of scarcity. DeBeers began taking control of the market in 1888, quickly forming a monopoly. It had an ambitious vision for the diamond market. DeBeers wanted to promote the stones as irreplaceable. Other gemstones have basically the same properties—hard, shiny rocks which make nice jewelry. As Edward Jay Epstein wrote in 1982: *The diamond invention is far more than a monopoly for fixing diamond prices; it is a mechanism for converting tiny crystals of carbon into universally recognized tokens of wealth, power, and romance. To achieve this goal, De Beers had to control demand as well as supply. Both women and men had to be made to perceive diamonds not as marketable precious stones but as an inseparable part of courtship and married life.*

Their ensuing role as winners in the diamond market is all down to clever marketing. Slogans such as “diamonds are forever” have cemented the monopoly. Note that the slogan applies to all diamonds, not their particular brand. Imagine if Apple made adverts declaring “phones are forever”. Or if McDonald’s made adverts saying “fast food is forever.” That’s how powerful DeBeers is. It can promote the entire market, knowing it will be the one to benefit. Throughout the twentieth century, DeBeer gave famous actresses diamond rings, pitched stories featuring the stones to magazines and incorporated their products into images of the British royal family. As their advertising agency, N. W. Ayer, explained, “There was no direct sale to be made. There was no brand name to be impressed on the public mind. There was simply an idea—the eternal emotional value surrounding the diamond.... The substantial diamond gift can be made a more widely sought symbol of personal and family success—an expression of socioeconomic achievement.”

The Impact of Technology

In our interconnected, globalized world, a few large firms continue to grow in power. Modern technology enables firms like Walmart to open branches all over the world. Without the barriers once associated with communication and supply networks, large firms can take over the local market anywhere they open. Small businesses have a very hard time competing.

When a new market appears, entrepreneurs rush to create products, services or technology. There is a flurry of activity for a few months or year. With time, customers gravitate toward the two or three companies they prefer. Starved of revenue, the other competitors shut down. Technology has exacerbated the growth of winner-take-all markets.

We are seeing this at the moment with ride-hailing services. In a once-crowded marketplace, two giant winners remain to take all the profits. It’s hard to say exactly why Uber and Lyft triumphed over numerous similar services. But it’s unlikely they will lose their market share anytime soon.

The same occurred with search engines. Google has now eliminated any meaningful competition. As their profits soar each year, even their nearest competitors—Yahoo, Bing—struggle. We can see from the example of Google how winner-take-all markets can self-perpetuate. Google is on top, so it gets the best employees, and has high research and development budgets. Google can afford to take risks and accumulate growing mountains of user data. Any losses or failures get absorbed. Consistent growth holds the trust of shareholders. Google essentially uses a form of Nassim Taleb’s barbell strategy. As Taleb writes in *The Black Swan*:

True, the Web produces acute concentration. A large number of users visit just a few sites, such as Google, which, at the time of this writing, has total market dominance. At no time in history has a company grown so dominant so quickly—Google can service people from

Nicaragua to southwestern Mongolia to the American West Coast, without having to worry about phone operators, shipping, delivery, and manufacturing. This is the ultimate winner-take-all case study. People forget, though, that before Google, Alta Vista dominated the search-engine market. I am prepared to revise the Google metaphor by replacing it with a new name for future editions of this book.

The role of data is particularly important. The more data a company has on its customers, the better equipped it is to release new products and market existing ones. Facebook has a terrifying amount of information about its users, so it can keep updating the social network to make it addictive and to lock people in. Newer or less popular social networks are working with less data and cannot compete for attention. A positive feedback loop forms for the entrenched companies. Facebook has a lot of data, and it can use that data to make the site more appealing. In turn, this more attractive Facebook leads people to spend more time clicking and generates even more data.²

Winner-take-all markets can be the result of lock-in. When the costs of switching between one supplier and another are too high to be worthwhile, consumers become locked in. Microsoft is a winner in the software market because most of the world is locked in to their products. As it stands, it would be nearly impossible for anyone to erode the market share Windows possesses. As Windows is copyrighted, no one can replicate it. Threatened by inconvenience, we become loyal to avoid incurring switching costs.

Marc Andreessen described the emergence of winner-take-all technology markets in 2013: *In normal markets, you can have Pepsi and Coke. In technology markets, in the long run, you tend to only have one.... The big companies, though, in technology tend to have 90 percent market share. So we think that generally, these are winner-take-all markets.*

Generally, number one is going to get like 90 percent of the profits. Number two is going to get like 10 percent of the profits, and numbers three through 10 are going to get nothing.

Leaders in certain areas are becoming winners and taking all because they can leverage small advantages, thanks to technology. In the past, an amazing teacher, singer, accountant, artist or stock broker could only reach a small number of people in their community. As their status grew, they would often charge more and choose to see fewer people, meaning their expertise became even more scarce. Now, however, those same top performers can reach a limitless audience through blogs, podcasts, videos, online courses and so on.

Think of it another way. For most of history we were limited to learning from the people in our community. Say you wanted to learn how to draw. You had access to your community art teacher. The odds they were the best art teacher in the world were extremely slim.

Now, however, you can go on the internet and access the best teacher in the world.

For most of history, comedians (or rather, their predecessors such as vaudeville performers) and musicians performed live. There was a distinct limit to how many shows they could do a year and how many people could attend each. So, there were many people at the top of each field, as many as needed to meet audience demand for performers. Now that we are no longer confined to live performances, we gravitate towards a few exceptional entertainers. Or consider the example of sports. Athletes were paid far more modest wages until TV allowed them to leverage their skills and reach millions of homes.

Having more information available offers us further incentives to pay attention only to the winners. Online, we can filter by popularity, look at aggregate reviews, select the first search option, or go with other people's preferences. With too many options, we google 'best Chinese restaurant near me' or 'best horror film 2016.' Sorting through all the options is too time-consuming, so the best stay as the best.

"In order to win, you must first survive."

— Warren Buffett

The Downsides of Winner-Take-All Markets

There are some serious downsides to winner-take-all markets. Economic growth and innovation rely on the emergence of new startups and entrepreneurs with disruptive ideas. When the gale of creative destruction stops blowing, industries stagnate. When a handful of winners control a market, they may discourage newcomers who cannot compete with established giants' budgets and power over the industry. According to some estimates, startups are failing faster and more frequently than in the past. Investors prefer established companies with secure short-term returns. Even when a startup succeeds, it tends to get acquired by a larger company. Apple, Amazon, Facebook and others acquire hundreds of companies each year.

Winner-take-all markets tend to discourage collaboration and cooperation. The winners have incentive to keep their knowledge and new data to themselves. Patents and copyright are liberally used to suppress any serious competition. Skilled workers are snapped up the second they leave education, and have powerful inducements to stay working for the winners. The result is a prisoner's dilemma-style situation. Although collaboration may be best for everyone, each individual organization benefits from being selfish. As a result, no one collaborates, they just compete.

The result is what Warren Buffett calls a "moat"—a substantial barrier against competition. Business moats come in many forms. Apple's superior brand identity is a moat, for example. It has taken enormous investments of resources to build and newer companies cannot compete. No number of Facebook adverts or billboards could replicate the kind of importance Apple has in our cultural consciousness. For other winners, the moat could be the ability to provide a product or service at a lower price than competitors, as with Amazon and Alibaba. Each of these has a great deal of market power and can influence prices. If Amazon drops their prices, competitors have no choice but to do the same and make less profit. If Apple decides to raise their prices, we are unlikely to buy our phones and laptops elsewhere and will pay a premium. As Greg Mankiw writes in *Principles of Microeconomics*, "Market power can cause markets to be inefficient because it keeps the price and quantity away from the equilibrium of supply and demand."

Luckily for us, winners tend to sow the seeds of their own destruction—but we'll save that for another article.

137. The Surprising Power of The Long Game

In a world where most people play the short game, playing the long game offers a huge advantage.

There is an old saying that I think of often, passed to me by my friend Peter Kaufman, “If you do what everyone else is doing, you shouldn’t be surprised to get the same results everyone else is getting.” Unless you’re lucky, doing what everyone else does ensures average results. The problem is we don’t want the same outcomes as everyone else. We want different outcomes. Different outcomes come from doing different things or doing things differently.

It’s easy to overestimate the importance of luck in success and underestimate the importance of investing in success every single day. Too often, we convince ourselves that success is just luck.

We tell ourselves the school teacher that left millions was just lucky. No. She wasn’t. She was playing a different game than you were. She was playing the long game.

Here’s the thing about the long game: It’s simpler to win than the short game. Simple but not easy. It requires repeatedly doing hard things today that make tomorrow easier.

We play the short game because we lack patience. Everyone wants to win, but there is a difference between trying to win the moment and trying to win the decade. As I’ve said before, a lack of patience changes the outcome.

The most successful people in any field all play the long game. The long game isn’t particularly notable. It doesn’t attract a lot of attention. In fact, from the outside, the long game looks boring. The tiny advantages that accrue aren’t noticed until success becomes too obvious to ignore.

The short game is intermittent. It’s as if Sisyphus pushes his huge boulder halfway up a steep hill, gets tired, lets it roll down the hill, and says to himself, “I’ll come back and do this tomorrow.” This is the human condition.

The Short Game

Immediate and visible benefits seduce you into the short game. You win today but lose tomorrow. The short game is taking advantage of your counterparties. The short game is spending more than you earn. The short game is not sleeping as much as you need to.

The short game is not investing in your relationships when you don’t need them.

The longer you play the short game, the harder things get.

Just as the accumulation of tiny advantages makes the future easier, the accumulation of tiny disadvantages makes the future harder.

If you take advantage of people, they won’t want to work with you. If you follow a get-rich-quick scheme, you end up back at zero. If you over-charge your customers, they will leave.

If you don’t invest in your relationship, you will come home to an empty house.

I like to explain it to my kids like this: Think of playing pool. Your goal is to run the table.

The short game sinks the first shot but doesn’t care where the ball goes next. You have the illusion of winning, but when you go to line up the next shot, you realize it’s harder than it needs to be.

Only when the costs become too large to ignore do people realize they played the wrong game.

The Long Game

The long game is the opposite of the short game. You have to think about where the ball ends up next.

From the outside, the long game looks pretty boring:

- Leaving the party early to make sure you get some sleep
- Eating healthy when everyone else is eating junk

- Investing your relationships every day so you have a foundation when something happens
- Going for a walk rather than watching Netflix
- Spending less than you make

... and countless other examples.

The long game isn't really debatable. Everyone knows; to get rich, we should spend less than we make and invest the difference and wait a long time. The formula isn't debatable. It just requires patience. The lack of patience changes the outcome.

The first step in the long game is the hardest. You have to be willing to suffer a little today in order to make tomorrow just a little bit easier. And you have to be smart enough to know that just because you can't see the tiny advantage you created doesn't mean it's not there.

Conclusion

Every action is a step toward the short game or the long game. You can't opt out, and you can't play a long-term game in everything. You need to pick what matters to you. But in everything you do, time amplifies the difference between strategies that work in the short term and ones that work in the long term.

The long game allows you to compound results. The longer you play, the bigger the rewards. The question to think about is when and where to play a long-term game. A good place to start is with things that compound: knowledge, relationships, and finances.

138. Entropy: The Hidden Force That Complicates Life

Entropy, a measure of disorder, explains why life always seems to get more, not less, complicated as time goes on.

The Order of Disorder

The second law of thermodynamics states that “as one goes forward in time, the net entropy (degree of disorder) of any isolated or closed system will always increase (or at least stay the same).”[1]

Entropy is a measure of disorder and affects all aspects of our daily lives. You can think of it as nature’s tax.[2]

Entropy naturally increases over time. Problems arise: your house gets messy, your garden gets weeds, and the heat from your coffee spreads out. Businesses fail, crimes and revolutions occur, and relationships end. In the long run, everything naturally decays, and disorder always increases.

Disorder is not a mistake; it is the default. Order is always artificial and temporary.

Discovery of Entropy

The identification of entropy is attributed to Rudolf Clausius (1822–1888), a German mathematician and physicist.

Clausius studied the conversion of heat into work. He recognized that heat from a body at a high temperature would flow to one at a lower temperature. This is how your coffee cools down the longer it’s left out — the heat from the coffee flows into the room. This happens naturally. But if you want to heat cold water to make the coffee, you need to do work — you need a power source to heat the water.

From this idea comes Clausius’s statement of the second law of thermodynamics: “Heat does not pass from a body at low temperature to one at high temperature without an accompanying change elsewhere.”

Clausius also observed something curious: Only a percentage of energy is converted into actual work. Nature was exerting a tax.

Perplexed, scientists asked, *where did the rest of the heat go and why?*

Clausius solved the riddle by observing a steam engine and calculating that energy spread out and left the system. In *The Mechanical Theory of Heat*, Clausius explains his findings: *... the quantities of heat which must be imparted to, or withdrawn from a changeable body are not the same, when these changes occur in a non-reversible manner, as they are*

when the same changes occur reversibly. In the second place, with each non-reversible change is associated an uncompensated transformation...

... I propose to call the magnitude S the entropy of the body... I have intentionally formed the word entropy so as to be as similar as possible to the word energy....

The second fundamental theorem [the second law of thermodynamics], in the form which I have given to it, asserts that all transformations occurring in nature may take place in a certain direction, which I have assumed as positive, by themselves, that is, without compensation... [T]he entire condition of the universe must always continue to change in that first direction, and the universe must consequently approach incessantly a limiting condition.

... For every body two magnitudes have thereby presented themselves—the transformation value of its thermal content [the amount of inputted energy that is converted to “work”], and its disgregation [separation or disintegration]; the sum of which constitutes its entropy.

Clausius summarized the concept of entropy in simple terms: “The energy of the universe is constant. The entropy of the universe tends to a maximum.”

The increase of disorder or entropy is what distinguishes the past from the future, giving a direction to time.

Stephen Hawking, *A Brief History of Time*

Entropy and Time

Entropy is one of the few concepts that provide evidence for the existence of time. The “Arrow of Time” is a name given to the idea that time is asymmetrical and flows in only one direction: forward. It is a non-reversible process wherein entropy increases.

Astronomer Arthur Eddington pioneered the concept of the Arrow of Time in 1927, writing: *Let us draw an arrow arbitrarily. If as we follow the arrow[,] we find more and more of the random element in the state of the world, then the arrow is pointing towards the future; if the random element decreases[,] the arrow points towards the past. That is the only distinction known to physics.*

In a segment of *Wonders of the Universe*, produced for BBC Two, physicist Brian Cox explains:

The Arrow of Time dictates that as each moment passes, things change, and once these changes have happened, they are never undone. Permanent change is a fundamental part of what it means to be human. We all age as the years pass by — people are born, they live, and they die. I suppose it’s part of the joy and tragedy of our lives, but out there in the universe, those grand and epic cycles appear eternal and unchanging. But that’s an illusion. See, in the life of the universe, just as in our lives, everything is irreversibly changing.

In his play *Arcadia*, Tom Stoppard uses a novel metaphor for the non-reversible nature of entropy:

When you stir your rice pudding, Septimus, the spoonful of jam spreads itself round making red trails like the picture of a meteor in my astronomical atlas. But if you stir backwards, the jam will not come together again. Indeed, the pudding does not notice and continues to turn pink just as before. Do you think this is odd?

Entropy in Business and Economics

Entropy is fundamentally a probabilistic idea: For every possible “usefully ordered” state of molecules, there are many more possible “disordered” states.

Just as energy tends towards a less useful, more disordered state, so do businesses and organizations. Rearranging the molecules — or business systems and people — into an “ordered” state requires constant energy expenditure.

Let's imagine that we start a company by sticking 20 people in an office with an ill-defined but ambitious goal and no further leadership. We tell them we'll pay them as long as they're there, working. We come back two months later to find that five have quit, five are sleeping with each other, and the other ten have no idea how to solve the litany of problems that have arisen. The employees are certainly not much closer to the goal laid out for them. Left to its own devices, the whole enterprise falls apart.

As a student of business administration, I know that there is a law of evolution for organizations as stringent and inevitable as anything in life. The longer one exists, the more it grinds out restrictions that slow its own functions. It reaches entropy in a state of total narcissism. Only the people sufficiently far out in the field get anything done, and every time they do, they are breaking half a dozen rules in the process.

Roger Zelazny, *Doorways in the Sand*

In physics, entropy is a law; in social systems, it's a mere tendency — though a strong one, to be sure.

Entropy occurs in every aspect of a business. Employees may forget training, lose enthusiasm, cut corners, and ignore rules. Equipment may break down, become inefficient, or be subject to improper use. Products may become outdated or be in less demand. Even the best of intentions cannot prevent an entropic slide towards chaos. Successful businesses invest time and money to minimize entropy. For example, they provide regular staff training, good reporting of issues, inspections, detailed files, and monitoring reports of successes and failures. They ruthlessly seek out and eliminate the sediment of bureaucracy. Anything less will mean almost inevitable problems and loss of potential revenue. Without the necessary effort, a business expands into bankruptcy. Entropy sows the seeds of destruction.

Fortunately, unlike thermodynamic systems, a business can reverse the impact of entropy. A balance must be struck between creativity and control, though. Too little autonomy for employees results in disinterest, while too much leads to poor decisions.

Entropy in Everyday Life

We have all observed entropy in our everyday lives. Everything tends towards disorder. Life always seems to get more complicated. Once-tidy rooms become cluttered and dusty. Strong relationships grow fractured and end. We grow old. Complex skills are forgotten. Buildings degrade as brickwork cracks, paint chips, and tiles loosen.

Disorder is not a mistake; it is the default. Order is always artificial and temporary.

Just because entropy is the natural tendency of things, that doesn't mean you can't fight back. You can clean a messy house, pull weeds out of the garden, and practice your skills. You can maintain your relationship, go to the gym, and even put up a fresh coat of paint. The ... ultimate purpose of life, mind, and human striving: to deploy energy and information to fight back the tide of entropy and carve out refuges of beneficial order.

Steven Pinker

Combatting entropy requires energy. When you clean a messy house, you use energy to return the house to a previous, simpler, tidier state. This is why entropy is nature's tax. You need to expend energy just to maintain the current state. Failing to pay nature's tax means things get more complicated, disorganized, and messier.

We cannot expect anything to stay the way we leave it. To maintain our health, relationships, careers, skills, knowledge, societies, and possessions requires never-ending effort and vigilance.

Now you understand why one of the hardest things in life is keeping it simple.

Disorder is not a mistake; it is our default. Order is always artificial and temporary.

Does that seem sad or pointless? It's not. Imagine a world with no entropy — everything stays the way we leave it, no one ages or gets ill, nothing breaks or fails, everything remains pristine. Arguably, that would also be a world without innovation, creativity, urgency, or need for progress.

In *The Information: A History, a Theory, a Flood*, James Gleick writes, *Organisms organize. ... We sort the mail, build sand castles, solve jigsaw puzzles, separate wheat from chaff, rearrange chess pieces, collect stamps, alphabetize books, create symmetry, compose sonnets and sonatas, and put our rooms in order... We propagate structure (not just we humans but we who are alive). We disturb the tendency toward equilibrium. It would be absurd to attempt a thermodynamic accounting for such processes, but it is not absurd to say we are reducing entropy, piece by piece. Bit by bit ... Not only do living things lessen the disorder in their environments; they are in themselves, their skeletons and their flesh, vesicles and membranes, shells, and carapaces, leaves, and blossoms, circulatory systems and metabolic pathways—miracles of pattern and structure. It sometimes seems as if curbing entropy is our quixotic purpose in the universe.* The question is not whether we can prevent entropy (we can't) but how we can curb, control, work with, and understand it. Entropy is all around us.

The tiny individual decisions we make (or don't make) to combat entropy in our daily lives create massively different results. Consider focus. The number of projects we are involved in only seems to grow. Those of us who expend energy to maintain focus on only one or two get a lot more done than those who naturally let things expand. Focus requires effort.

Using Entropy to Gain an Advantage

Whether you're starting a business or trying to change your organization, understanding the abstraction of entropy as a mental model will help you accomplish your goals more effectively. Because things naturally move to disorder over time, we can position ourselves to create stability.

There are two types of stability: active and passive. Consider a ship, which, if designed well, should be able to sail through a storm without intervention. This is passive stability. A fighter jet, in contrast, requires active stability. The plane can't fly for more than a few seconds without having to adjust its wings. This adjustment happens so fast that it's controlled by software. There is no inherent stability here: if you cut the power, the plane crashes.[3]

People get in trouble when they confuse the two types of stability.

Relationships, for example, require attention and care. If you assume your relationship is passively stable, you'll wake up one day to divorce papers. Your house is also not passively stable. If not cleaned regularly, it will continue to get messier and messier.

Organizations require stability, as well. If you're a company that relies on debt, you're not passively stable but actively stable. Factoring in a margin of safety, this means that the people giving you the credit should be passively stable. If you're both actively stable, then when the power gets cut, you're likely to be in a position of weakness, not strength.

With active stability, you're applying energy to a system to bring about some advantage (keeping the plane from crashing, your relationship going, the house clean, etc.). If we move a little further down the rabbit hole, we can see how applying the same amount of energy can yield totally different results.

Let's use the analogy of coughing.[4] Coughing is the transfer of energy as heat. If you cough in a quiet coffee shop, which you can think of as a system with low entropy, you cause a big change. Your cough is disruptive. On the other hand, if you cough in Times Square, a system with a lot of entropy, that same cough will have no impact. While you change the entropy in both cases, the impact you have with the same cough is proportional to the existing entropy.

Now think of this example in relation to your organization. You're applying energy to get something done. The higher the entropy in the system, the less efficient the energy you

apply will be. The same person applying 20 units of energy in a big bureaucracy is going to see less impact than someone applying the same 20 units in a small startup.

You can think about this idea in a competitive sense, too. If you're starting a business and you're competing against very effective and efficient people, a lot of effort will get absorbed. It's not going to be very efficient. If, on the other hand, you compete against less efficient and effective people, the same amount of energy will be more efficient in its conversion.

For a change to occur, you must apply more energy to the system than is extracted by the system.

139. Resonance: How to Open Doors For Other People

It's only polite.

Hold the door open for others, and they will open doors for you.

We are far more interdependent than we would like to admit. We biologically need to connect. "Limbic resonance" is a term used by Thomas Lewis, Fari Amini, and Richard Lannon in their book, *A General Theory of Love*, to express the ability to share deep emotional states. The name comes from the limbic system, the set of structures in our brains which appear to be responsible for our emotions, among other things.

Resonance is not only a mammalian capacity but an outright necessity. Our infants will die if not provided with the warmth of connection with another being, despite being provided with all their physiological needs. This has been illustrated in inhumane 13th-century human 'experiments' by Frederick the Great depriving babies of human connection, and more recently by Harry Harlow in rhesus monkeys. Baby monkeys choose to spend 17 hours a day with a soft cloth mother figure that does not provide food compared to only one hour a day with a wire mother figure that actually provides milk. Connection is a far superior sustenance.

An oft-quoted study by psychologist John Gottman suggests a partner's ability to answer "emotional bids" to be strongly predictive of divorce. The divorce rate is higher in couples where partners do not resonate or fail to engage and respond to requests for attention. Those who divorced after a six-year follow-up were observed to have turned towards the other on only 30% of occasions a bid was made, whilst couples who were still together averaged closer to 90%. Furthermore, in *A General Theory of Love*, the authors convincingly argue that what we are actually doing is synchronising ourselves with one another, with deep impacts on our emotional and physical health.

This would be in keeping with the results of the well-known Harvard Study of Adult Development, which followed a large cohort of people over a lifetime. These types of studies are rare because they're expensive and hard to carry out. This study was well worth investing in, with one clear overall conclusion: good relationships keep us happier and healthier. Its director, psychiatrist Robert Waldinger, states:

Well, the lessons aren't about wealth or fame or working harder and harder. The clearest message that we get from this 75-year study is this: Good relationships keep us happier and healthier. Period.

We've learned three big lessons about relationships. The first is that social connections are really good for us, and that loneliness kills. It turns out that people who are more socially connected to family, to friends, to community, are happier, they're physically healthier, and they live longer than people who are less well connected. And the experience of loneliness turns out to be toxic. People who are more isolated than they want to be from others find that they are less happy, their health declines earlier in midlife, their brain functioning declines sooner and they live shorter lives than people who are not lonely.

So what now? Where does that leave us?

People feel connected when they are understood and appreciated. My friend's aunt taught her this when they walked together down a busy road. Her aunt stopped to talk to a homeless man. With no money to give him, she started asking questions about his dog, chatting to him about her own dog. The interaction took 30 seconds. The man's eyes shone back bright, engaged. As they walked away, my friend's aunt whispered, "People want to be recognized. It reminds them they exist. Never take that away from anyone."

Lesson learned.

Listen, Summarize, Show

I work hard to live that lesson through the following: listen, summarize, show. True, sustained listening is one of the hardest skills to achieve. I've met only a handful of people

with the ability. A simple way to focus your attention is to *listen* with the intention of *summarizing* the other person's point of view. This stops you from using your mental energy to work out your reply, and helps store the other's words in your memory as well as identify any gaps in your understanding so you can ask questions to clarify.

The nature of these questions in themselves will *show* to the other person that they are heard and effort is being made to take them seriously. Just as it is not enough to know, when it comes to human relationships, it is not enough to understand. What is crucial is to show you understand. If empathy is recognizing another's perspective, consideration for the other needs to be externalized from you for it to exist and build rapport.

Summarizing and asking questions is a way of feeding back your resonance. Cutting short the conversation, stating opinions, value judgements, your own solutions, or even a lazy "I see" or "interesting" does not demonstrate resonance. In fact, you can use "I understand" as a red flag for someone who does not understand. Often, this is followed by an action that shows a thorough lack of comprehension.

Connect Where It Matters

To resonate with others, we need to connect when it matters. This nurtures both us and others, and also earns trust. Just as in cooking, timing is everything.

This is where the metaphorical doors come in. How do you feel when someone holds the door open for you—especially when you've got your hands full? When would you hold open a door for another person?

We may kindly open a door, to find the person has no intention of walking through it and continues down the stairwell because they're heading to the floor below. In this case, we did not understand their needs. We may even find ourselves bending over backwards for another, without consequence. This is the equivalent of opening doors willy-nilly down a long corridor without anyone walking through them.

At worst, we might inadvertently (or dare I say, even intentionally) slam a door in someone's face. That will hurt—even more so if we had offered to hold it for them and they were counting on it to be open. Holding a door open at the right time represents tending to a perceived need and meeting expectations.

All people want to be understood and appreciated. By connecting in this way, they trust you understand them and are actually looking out for their interests. You are attentive and willing to open doors for them. The power of resonance will keep you happy and healthy and open doors for you.

140. Illusion of Transparency: Your Poker Face is Better Than You Think

We tend to think that people can easily tell what we're thinking and feeling. They can't.

Understanding the illusion of transparency bias can improve relationships, job performance, and more.

"A wonderful fact to reflect upon, that every human creature is constituted to be that profound secret and mystery to every other." — Charles Dickens, A Tale of Two Cities

When we experience strong emotions, we tend to think it's obvious to other people, especially those who know us well. When we're angry or tired or nervous or miserable, we may assume that anyone who looks at our face can spot it straight away.

That's not true. Most of the time, other people can't correctly guess what we're thinking or feeling. Our emotions are not written all over our face all the time. The gap between our subjective experience and what other people pick up on is known as the illusion of transparency. It's a fallacy that leads us to overestimate how easily we convey our emotions and thoughts.

For example, you arrive at the office exhausted after a night with too little sleep. You drift around all day, chugging espressos, feeling sluggish and unfocused. Everything you do seems to go wrong. At the end of the day, you sheepishly apologize to a coworker for being "useless all day."

They look at you, slightly confused. 'Oh,' they say. 'You seemed fine to me.' Clearly, they're just being polite. There's no way your many minor mistakes during the day could have escaped their notice. It must be extra apparent considering your coworkers all show up looking fresh as a daisy every single day.

Or imagine that you have to give a talk in front of a big crowd and you're terrified. As you step on stage, your hands shake, your voice keeps catching in your throat, you're sweating and flushed. Afterward, you chat to someone from the audience and remark: 'So that's what a slow-motion panic attack looks like.'

'Well, you seemed like a confident speaker,' they say. 'You didn't look nervous at all. I wish I could be as good at public speaking.' Evidently, they were sitting at the back or they have bad eyesight. Your shaking hands and nervous pauses were far too apparent. Especially compared to the two wonderful speakers who came after you.

No one cares

"Words are the source of misunderstandings." — Antoine de Saint-Exupéry, The Little Prince

The reality is that other people pay much less attention to you than you think. They're often far too absorbed in their own subjective experiences to pick up on subtle cues related to the feelings of others. If you're annoyed at your partner, they're probably too busy thinking about what they need to do at work tomorrow or what they're planning to cook for dinner to scrutinize your facial expressions. They're not deliberately ignoring you, they're just thinking about other things. While you're having a bad day at work, your coworkers are probably distracted by their own deadlines and personal problems. You could fall asleep sitting up and many of them wouldn't even notice. And when you give a talk in front of people, most of them are worrying about the next time they have to do any public speaking or when they can get a coffee.

In your own subjective experience, you're in the eye of the storm. But what other people have to go on are things like your tone of voice, facial expressions, and body language. The clues these provide can be hard to read. Unless someone is trying their best to figure out what you're thinking or feeling, they're not going to be particularly focused on your body language. If you make even the slightest effort to conceal your inner state, you're quite able to hide it altogether from everyone.

Our tendency to overestimate how much attention people are paying to us is a result of seeing our own perspective as the only perspective. If we're feeling a strong emotion, we assume other people care about how we feel as much as we do. This egocentric bias leads to the spotlight effect—in social situations, we feel like there's a spotlight shining on us. It's not self-obsession, it's natural. But overall, this internal self-focus is what makes you think other people can tell what you're thinking.

Take the case of lying. Even if we try to err on the side of honesty, we all face situations where we feel we have no option except to tell a lie. Setting aside the ethics of the matter, most of us probably don't feel good about lying. It makes us uncomfortable. It's normal to worry that whoever you're lying to will easily be able to tell. Again, unless you're being very obvious, the chances of someone else picking up on it are smaller than you think. In one study, participants asked to lie to other participants estimated they'd be caught about half the time. In fact, people only guessed they were lying about a quarter of the time—a rate low enough for random chance to account for it.

Tactics

“Even if one is neither vain nor self-obsessed, it is so extraordinary to be oneself—exactly oneself and no one else—and so unique, that it seems natural that one should also be unique for someone else.” — Simone de Beauvoir

Understanding how the illusion of transparency works can help you navigate otherwise challenging situations with ease.

Start with accepting that other people don't usually know what you're thinking and feeling. If you want someone to know your mental state, you need to tell them in the clearest terms possible. You can't make assumptions. Being subtle about your feelings is not the best idea, especially in high-stakes situations. Err on the side of caution whenever possible by communicating plainly in words about your feelings or views.

Likewise, if you think you know how someone else feels, you should ask them to confirm. You shouldn't assume you've got it right—you probably haven't. If it's important, you need to double check. The person who seems calm on the surface might be frenzied underneath. Some of us just appear unhappy to others all the time, no matter how we're feeling. If you can't pick up on someone's mental state, they might not be vocalizing it because they think it's obvious. So ask.

As Dylan Evans writes in *Risk Intelligence: How To Live With Uncertainty*,

The first and most basic remedy is simply to treat all your hunches about the thoughts and feelings of other people with a pinch of salt and to be similarly skeptical about their ability to read your mind. It can be hard to resist the feeling that someone is lying to you, or that your own honesty will shine through, but with practice it can be done.

The illusion of transparency doesn't go away just because you know someone well. Even partners, family members and close friends have difficulty reading each other's mental states. The problem compounds when we think they should be able to do this. We can easily become annoyed when they can't. If you're upset or angry and someone close to you doesn't make any attempt to make you feel better, they are not necessarily ignoring you. They just haven't noticed anything is wrong, or they may not know how you want them to respond. As Hanlon's razor teaches us, it's best not to assume malicious intent. Understanding this can help avoid arguments that spring up based on thinking we're communicating clearly when we're not.

“Much unhappiness has come into the world because of bewilderment and things left unsaid.” — Fyodor Dostoevsky

Set yourself free

Knowing about the illusion of transparency can be liberating. Guess what? No one really cares. Or almost no one. If you've got food stuck between your teeth or you stutter during a speech or you're exhausted at work, you might as well assume no one has noticed. Most of the time, they haven't.

Back to public speaking: We get it all wrong when we think people can tell we're nervous about giving a talk. In a study entitled "The illusion of transparency and the alleviation of speech anxiety," Kenneth Savitsky and Thomas Gilovich tested how knowing about the effect could help people feel less scared about public speaking.¹ When participants were asked to give a speech, their self-reported levels of nervousness were well above what audience members guessed they were experiencing. Inside, they felt like a nervous wreck. On the outside, they looked calm and collected.

But when speakers learned about the illusion of transparency beforehand, they were less concerned about audience perceptions and therefore less nervous. They ended up giving better speeches, according to both their own and audience assessments. It's a lot easier to focus on what you're saying if you're not so worried about what everyone else is thinking.

The sun revolves around me, doesn't it?

In psychology, anchoring refers to our tendency to make an estimated guess by selecting whatever information is easily available as our "anchor," then adjusting from that point. Often, the adjustments are insufficient. This is exactly what happens when you try to guess the mental state of others. If we try to estimate how a friend feels, we take how we feel as our starting point, then adjust our guess from there.

According to the authors of a paper entitled "The Illusion of Transparency: Biased Assessments of Other's Ability to Read One's Emotional States,"

People are typically quite aware of their own internal states and tend to focus on them rather intently when they are strong. To be sure, people recognize that others are not privy to the same information as they are, and they attempt to adjust for this fact when trying to anticipate another's perspective. Nevertheless, it can be hard to get beyond one's own perspective even when one knows that.

This is similar to hindsight bias, where things seem obvious in retrospect, even if they weren't beforehand. When you look back on an event, it's hard to disentangle what you knew then from what you know now. You can only use your current position as an anchor, a perspective which is inevitably skewed.

If you're trying to hide your mental state, you're probably doing better than you think. Unless you're talking to, say, a trained police interrogator or professional poker player, other people are easy to fool. They're not looking that hard, so a mild effort to hide your emotions is likely to work well. People can't read your mind, whether you're trying to pretend you don't hate the taste of a trendy new beer, or trying to conceal your true standing in a negotiation to gain more leverage.

The illusion of transparency explains why, even once you're no longer a teenager, it still seems like few people understand you. It's not that other people are ambivalent or confused. Your feelings just aren't as clear as you think. Often you can't see beyond the confines of your own head and neither can anyone else. It's best to make allowances for that.

141. How to Use Occam's Razor Without Getting Cut

Occam's razor is one of the most useful, (yet misunderstood,) models in your mental toolbox to solve problems more quickly and efficiently. Here's how to use it.

Occam's razor (also known as the "law of parsimony") is a problem-solving principle which serves as a useful mental model. A philosophical razor is a tool used to eliminate improbable options in a given situation. Occam's is the best-known example.

Occam's razor can be summarized as follows:

Among competing hypotheses, the one with the fewest assumptions should be selected.

The Basics

In simpler language, Occam's razor states that the simplest explanation is preferable to one that is more complex. Simple theories are easier to verify. Simple solutions are easier to execute.

In other words, we should avoid looking for excessively complex solutions to a problem, and focus on what works given the circumstances. Occam's razor can be used in a wide range of situations, as a means of making rapid decisions and establishing truths without empirical evidence. It works best as a mental model for making initial conclusions before the full scope of information can be obtained.

Science and math offer interesting lessons that demonstrate the value of simplicity. For example, the principle of minimum energy supports Occam's razor. This facet of the second law of thermodynamics states that wherever possible, the use of energy is minimized. Physicists use Occam's razor in the knowledge that they can rely on everything to use the minimum energy necessary to function. A ball at the top of a hill will roll down in order to be at the point of minimum potential energy. The same principle is present in biology. If a person repeats the same action on a regular basis in response to the same cue and reward, it will become a habit as the corresponding neural pathway is formed. From then on, their brain will use less energy to complete the same action.

The History of Occam's Razor

The concept of Occam's razor is credited to William of Ockham, a 14th-century friar, philosopher, and theologian. While he did not coin the term, his characteristic way of making deductions inspired other writers to develop the heuristic. Indeed, the concept of Occam's razor is an ancient one. Aristotle produced the oldest known statement of the concept, saying, "We may assume the superiority, other things being equal, of the demonstration which derives from fewer postulates or hypotheses."

Robert Grosseteste expanded on Aristotle's writing in the 1200s, declaring

That is better and more valuable which requires fewer, other circumstances being equal.... For if one thing were demonstrated from many and another thing from fewer equally known premises, clearly that is better which is from fewer because it makes us know quickly, just as a universal demonstration is better than particular because it produces knowledge from fewer premises. Similarly, in natural science, in moral science, and in metaphysics the best is that which needs no premises and the better that which needs the fewer, other circumstances being equal.

Nowadays, Occam's razor is an established mental model which can form a useful part of a latticework of knowledge.

Examples of the Use of Occam's Razor

The Development of Scientific Theories

Occam's razor is frequently used by scientists, in particular for theoretical matters. The simpler a hypothesis is, the more easily it can be proven or falsified. A complex explanation for a phenomenon involves many factors which can be difficult to test or lead to issues with the repeatability of an experiment. As a consequence, the simplest solution which is consistent with the existing data is preferred. However, it is common for new data to allow hypotheses to become more complex over time. Scientists choose to opt for the simplest solution as the current data permits, while remaining open to the possibility of future research allowing for greater complexity.

The version used by scientists can best be summarized as:

When you have two competing theories that make exactly the same predictions, the simpler one is better.

The use of Occam's razor in science is also a matter of practicality. Obtaining funding for simpler hypotheses tends to be easier, as they are often cheaper to prove.

Albert Einstein referred to Occam's razor when developing his theory of special relativity. He formulated his own version: "It can scarcely be denied that the supreme goal of all

theory is to make the irreducible basic elements as simple and as few as possible without having to surrender the adequate representation of a single datum of experience.” Or, “Everything should be made as simple as possible, but not simpler.”

The physicist Stephen Hawking advocates for Occam’s razor in *A Brief History of Time*: *We could still imagine that there is a set of laws that determines events completely for some supernatural being, who could observe the present state of the universe without disturbing it. However, such models of the universe are not of much interest to us mortals. It seems better to employ the principle known as Occam’s razor and cut out all the features of the theory that cannot be observed.*

Isaac Newton used Occam’s razor too when developing his theories. Newton stated: “We are to admit no more causes of natural things than such as are both true and sufficient to explain their appearances.” He sought to make his theories, including the three laws of motion, as simple as possible, with only the necessary minimum of underlying assumptions.

Medicine

Modern doctors use a version of Occam’s razor, stating that they should look for the fewest possible causes to explain their patient’s multiple symptoms, and give preference to the most likely causes. A doctor we know often repeats the aphorism that “common things are common.” Interns are instructed, “when you hear hoofbeats, think horses, not zebras.” For example, a person displaying influenza-like symptoms during an epidemic would be considered more likely to be suffering from influenza than an alternative, rarer disease. Making minimal diagnoses reduces the risk of over-treating a patient, causing panic, or causing dangerous interactions between different treatments. This is of particular importance within the current medical model, where patients are likely to see numerous health specialists and communication between them can be poor.

Prison Abolition and Fair Punishment

Occam’s razor has long played a role in attitudes towards the punishment of crimes. In this context, it refers to the idea that people should be given the least punishment necessary for their crimes. This is to avoid the excessive penal practices which were popular in the past. For example, a 19th-century English convict could receive five years of hard labor for stealing a piece of food.

The concept of penal parsimony was pioneered by Jeremy Bentham, the founder of utilitarianism. He held that punishments should not cause more pain than they prevent. Life imprisonment for murder could be seen as justified in that it might prevent a great deal of potential pain, should the perpetrator offend again. On the other hand, long-term imprisonment of an impoverished person for stealing food causes substantial suffering without preventing any.

Bentham’s writings on the application of Occam’s razor to punishment led to the prison abolition movement and many modern ideas related to rehabilitation.

Exceptions and Issues

It is important to note that, like any mental model, Occam’s razor is not foolproof. Use it with care, lest you cut yourself. This is especially crucial when it comes to important or risky decisions. There are exceptions to any rule, and we should never blindly follow the results of applying a mental model which logic, experience, or empirical evidence contradict. When you hear hoofbeats behind you, in most cases you should think horses, not zebras—unless you are out on the African savannah.

Furthermore, simple is as simple does. A conclusion can’t rely just on its simplicity. It must be backed by empirical evidence. And when using Occam’s razor to make deductions, we must avoid falling prey to confirmation bias. In the case of the NASA moon landing conspiracy theory, for example, some people consider it simpler for the moon landing to have been faked, others for it to have been real. Lisa Randall best expressed the issues

with the narrow application of Occam's razor in her book, *Dark Matter and the Dinosaurs: The Astounding Interconnectedness of the Universe*:

Another concern about Occam's Razor is just a matter of fact. The world is more complicated than any of us would have been likely to conceive. Some particles and properties don't seem necessary to any physical processes that matter—at least according to what we've deduced so far. Yet they exist. Sometimes the simplest model just isn't the correct one.

This is why it's important to remember that opting for simpler explanations still requires work. They may be easier to falsify, but still require effort. And that the simpler explanation, although having a higher chance of being correct, is not always true.

Occam's razor is not intended to be a substitute for critical thinking. It is merely a tool to help make that thinking more efficient. Harlan Coben has disputed many criticisms of Occam's razor by stating that people fail to understand its exact purpose:

Most people oversimplify Occam's razor to mean the simplest answer is usually correct.

But the real meaning, what the Franciscan friar William of Ockham really wanted to emphasize, is that you shouldn't complicate, that you shouldn't "stack" a theory if a simpler explanation was at the ready. Pare it down. Prune the excess.

Remember, Occam's razor is complemented by other mental models, including fundamental error distribution, Hanlon's razor, confirmation bias, availability heuristic and hindsight bias. The nature of mental models is that they tend to all interlock and work best in conjunction.

142. Survivorship Bias: The Tale of Forgotten Failures

Survivorship bias is a common logical error that distorts our understanding of the world. It happens when we assume that success tells the whole story and when we don't adequately consider past failures.

There are thousands, even tens of thousands of failures for every big success in the world. But stories of failure are not as sexy as stories of triumph, so they rarely get covered and shared. As we consume one story of success after another, we forget the base rates and overestimate the odds of real success.

"See," says he, "you who deny a providence, how many have been saved by their prayers to the Gods."

"Ay," says Diagoras, "I see those who were saved, but where are those painted who were shipwrecked?"

— Cicero

The Basics

A college dropout becomes a billionaire. Batuli Lamichhane, a chain-smoker, lives to the age of 118. Four young men are rejected by record labels and told "guitar groups are on the way out," then go on to become the most successful band in history.

Bill Gates, Batuli Lamichhane, and the Beatles are oft-cited examples of people who broke the rules without the expected consequences. We like to focus on people like them—the result of a cognitive shortcut known as survivorship bias.

When we only pay attention to those who survive, we fail to account for base rates and end up misunderstanding how selection processes actually work. The base rate is the probability of a given result we can expect from a sample, expressed as a percentage. If you play roulette, for example, you can be expected to win one out of 38 games, or 2.63%, which is the base rate. The problem arises when we mistake the winners for the rule and not the exception. People like Gates, Lamichhane, and the Beatles are anomalies at one end of a distribution curve. While there is much to learn from them, it would be a mistake to expect the same results from doing the same things.

A stupid decision that works out well becomes a brilliant decision in hindsight.

— Daniel Kahneman

Cause and Effect

Can we achieve anything if we try hard enough? Not necessarily. Survivorship bias leads to an erroneous understanding of cause and effect. People see correlation in mere coincidence. We all love to hear stories of those who beat the odds and became successful, holding them up as proof that the impossible is possible. We ignore failures in pursuit of a coherent narrative about success.

Few would think to write the biography of a business person who goes bankrupt and spends their entire life in debt. Or a musician who tried again and again to get signed and was ignored by record labels. Or of someone who dreams of becoming an actor, moves to LA, and ends up returning a year later, defeated and broke. After all, who wants to hear that? We want the encouragement survivorship bias provides, and the subsequent belief in our own capabilities. The result is an inflated idea of how many people become successful. The discouraging fact is that success is never guaranteed. Most businesses fail. Most people do not become rich or famous. Most leaps of faith go wrong. It does not mean we should not try, just that we should be realistic with our understanding of reality.

Beware of advice from the successful.

— Barnaby James

Survivorship Bias in Business

Survivorship bias is particularly common in the world of business. Companies which fail early on are ignored, while the rare successes are lauded for decades. Studies of market performance often exclude companies which collapse. This can distort statistics and make success seem more probable than it truly is. Just as history is written by the winners, so is much of our knowledge about business. Those who end up broke and chastened lack a real voice. They may be blamed for their failures by those who ignore the role coincidence plays in the upward trajectories of the successful.

Nassim Taleb writes of our tendency to ignore the failures: "We favor the visible, the embedded, the personal, the narrated, and the tangible; we scorn the abstract." Business books laud the rule-breakers who ignore conventional advice and still create profitable enterprises. For most entrepreneurs, taking excessive risks and eschewing all norms is an ill-advised gamble. Many of the misfit billionaires who are widely celebrated succeeded in spite of their unusual choices, not because of them. We also ignore the role of timing, luck, connections and socio-economic background. A person from a prosperous family, with valuable connections, who founds a business at a lucrative time has a greater chance of survival, even if they drop out of college or do something unconventional. Someone with a different background, acting at an inopportune time, will have less of a chance.

In *No Startup Hipsters: Build Scalable Technology Companies*, Samir Rath and Teodora Georgieva write:

Almost every single generic presentation for startups starts with "Ninety Five percent of all startups fail", but very rarely do we pause for a moment and think "what does this really mean?" We nod our heads in somber acknowledgement and with great enthusiasm turn to the heroes who "made it" — Zuckerberg, Gates, etc. to absorb pearls of wisdom and find the Holy Grail of building successful companies. Learning from the successful is a much deeper problem and can reduce the probability of success more than we might imagine. Examining the lives of successful entrepreneurs teaches us very little. We would do far better to analyze the causes of failure, then act accordingly. Even better would be learning from both failures and successes.

Focusing on successful outliers does not account for base rates. As Rath and Georgieva go on to write:

After any process that picks winners, the non-survivors are often destroyed or hidden or removed from public view. The huge failure rate for start-ups is a classic example; if failures become invisible, not only do we fail to recognise that missing instances hold important information, but we may also fail to acknowledge that there is any missing information at all.

They describe how this leads us to base our choices on inaccurate assumptions:

Often, as we revel in stories of start-up founders who struggled their way through on cups of ramen before the tide finally turned on viral product launches, high team performance or strategic partnerships, we forget how many other founders did the same thing, in the same industry and perished...The problem we mention is compounded by biographical or autobiographical narratives. The human brain is obsessed with building a cause and effect narrative. The problem arises when this cognitive machinery misfires and finds patterns where there are none.

These success narratives are created both by those within successful companies and those outside. Looking back on their ramen days, founders may believe they had a plan all along. They always knew everything would work out. In truth, they may lack an idea of the cause and effect relationships underlying their progress. When external observers hear their stories, they may, in a quasi-superstitious manner, spot "signs" of the success to come. As Daniel Kahneman has written, the only true similarity is luck.

Consider What You Don't See

When we read about survivorship bias, we usually come across the archetypical story of Abraham Wald, a statistician studying World War II airplanes. His research group at

Columbia University was asked to figure out how to better protect airplanes from damage. The initial approach to the problem was to look at the planes coming back, seeing where they were hit the worst, then reinforcing that area.

However, Wald realized there was a missing, yet valuable, source of evidence: Planes that were hit that did not make it back. Planes that went down, that weren't surviving, had much better information to provide on areas that were most important to reinforce. Wald's approach is an example of how to overcome survivorship bias. Don't look just at what you can see. Consider all the things that started on the same path but didn't make it. Try to figure out their story, as there is as much, if not more, to be learned from failure.

Considering survivorship bias when presented with examples of success is difficult. It is not instinctive to pause, reflect, and think through what the base rate odds of success are and whether you're looking at an outlier or the expected outcome. And yet if you don't know the real odds, if you don't know if what you're looking at is an example of survivorship bias, then you've got a blind spot.

Whenever you read about a success story in the media, think of all the people who tried to do what that person did and failed. Of course, understanding survivorship bias isn't an excuse for not taking action, but rather an essential tool to help you cut through the noise and understand the world. If you're going to do something, do it fully informed.

143. Tradeoffs: The Currency of Decision Making

Every decision we make carries an opportunity cost. If we don't budget wisely, we end up wasting time and energy on things that don't matter. Here's how to do it right.

The disregard of tradeoffs and opportunity costs play out in the same pattern again and again in our lives. We try to do everything and end up accomplishing nothing.

If you're young, you think you can go all out in your career, have fulfilling relationships, travel on a regular basis, keep up with reading and social media, go without sleep, take out unnecessary credit card debt, and start a family at the same time. The end result is always a total meltdown.

Even if you are twenty or thirty years past this point, you are not immune. Every day we are faced with choices on how to invest our time, and we all can be guilty of the same thing: Taking on too much without properly understanding the costs. The problem is a misunderstanding of the importance of tradeoffs.

It's not always that we need to do more but rather that we need to focus on less.

Nathan W. Morris

The Dismal Science

Economics is all about tradeoffs. A tradeoff is loosely defined as any situation where making one choice means losing something else, usually forgoing a benefit or opportunity. We experience tradeoffs in zero-sum situations when a plus in one area must be a negative in another. A core component of economic theory is the study of how we allocate scarce resources and negotiate opportunity costs.

Economics offers tools that we can use as guides for getting what we want out of life if we take economic lessons and apply them to resources other than money. We all know our money isn't infinite, yet we end up treating our time and energy and attention as if they are. Many of us act as if there are no tradeoffs—we can just do everything if we try hard enough. The irony is that those who know how to make tradeoffs can get so much more out of life than those who try to get everything.

Economics teaches you that making a choice means giving up something.

Russ Roberts

That's not to say we can't get more out of our time investments while staying within the limitations imposed by mental and physical health. We can get more efficient in certain areas. We can combine activities. We can decide to focus on one area for a while, then switch to another. We can find plenty of smart ways to achieve more.

But blindly trying to overstuff our days and stretch our minds to their limits is foolish, whatever the self-help gurus and hustle porn promoters claim. We're sold the false belief that we can be and have everything. As Julian Baggini writes in What's It All About?: Philosophy & the Meaning of Life, a person in a content, long-term relationship might feel the pressure to get everything right:

They may well be an excellent life partner. But perhaps they are not a sexual athlete, the world's best communicator, the possessor of a great body, a domestic god or goddess. In their local bookshop, however, they will be told by a book that they can and perhaps should be all of these things. This can foster feelings of inadequacy.

The truth is, when you're trying to get everything right, you're getting nothing right.

No One Has Everything

When we look at other people, we end up getting the impression that they are managing to do everything. They are fantastic parents, their relationships are novel-worthy, they look amazing, their careers are epic, they get enough sleep, and they feel good all the time.

This, however, is far from true. We're just not seeing the hidden tradeoffs they're making.

Tradeoffs can take a while to become apparent. They sometimes only show up in the long term. We see this in complex adaptive systems. Try to optimize one area and there's likely to be a price elsewhere. Sometimes it's an obvious negative equation, like when steroid abuse leads to organ damage, or when fancy houses mask crippling debt.

But often the tradeoffs are genuinely hard to evaluate—people with world-class math abilities are often socially clueless, and many parents sacrifice career advancement to raise their kids. We all have to make sacrifices to be able to invest in what is important to us. Tradeoffs imply that to get really great at a few things, you have to accept being mediocre at a lot more.

There are no solutions. There are only trade-offs.

Thomas Sowell

Most of us can divide up our lives into a few important areas: work, health, family, relationships, friends, hobbies, and so on. It's an unfortunate truism that we can never quite keep everything in balance. We're constantly going off-kilter in one area or another and having to make course corrections. When one area goes well, another is usually sliding. It's like a game of whack-a-mole. Focus on one area and it's often to the detriment of another.

If you feel like you're always behind in some area of your life, it's probably a sign to reconsider tradeoffs. If you feel like you're always running in place without making any serious progress on anything you care about, you're probably making the wrong tradeoffs. We often end up allocating our time, and other scarce resources like money, by default, not in the way that gets us what we want.

The necessity of making trade-offs alters how we feel about the decisions we face; more important, it affects the level of satisfaction we experience from the decisions we ultimately make.

Barry Schwartz, *The Paradox of Choice: Why More Is Less*

How to take tradeoffs into account

One of the most important areas where we need to pay attention to tradeoffs is when we make decisions. It's not always enough to consider what we stand to gain from going for option B over option A. We also need to take into account what we lose.

Most big decisions involve major tradeoffs. That's not necessarily a bad thing. It's neutral. It's just the price we pay. Simply being aware of the notion of tradeoffs is enough to change the way we make decisions.

Time is our most fundamental constraint. If you use an hour for one thing, you can't use it for anything else. Time passes, whatever we do with it. It seems beneficial then to figure out the means of using it with the lowest possible opportunity costs. One of the simplest ways to do this is to establish how you'd like to be using your time, then track how you're using it for a week. Many people find a significant discrepancy. Once we see the gulf between the tradeoffs we're making and the ones we'd rather be making, it's easier to work on changing that.

For instance, understanding tradeoffs in time usage is a good way to cut out unwanted, unhelpful behaviors and wastage. It's one thing to tell yourself you're not going to spend half an hour reading the news every morning before starting work. It's another matter to plan how you're going to spend that time instead. Will you finish work earlier and cook a fancier dinner, or Skype with a friend who lives abroad, or read a chapter of a book?

The higher the value is of what you could be doing versus what you are doing, the greater the opportunity cost. We'd all agree that we'd rather devote our time to activities we value, yet we can end up not acting that way out of habit or obligation or simply because we

haven't considered what we're forgoing. We will never manage to get rid of everything that has low value to us, but we can keep cutting it back.

Multitasking is a way of getting more out of our time without making tradeoffs doesn't work. The tradeoff, in that case, is often not doing anything particularly well. If you answer emails when you're with your kids or friends, you're not really focusing on either. Your emails are banal and the people you are with feel unimportant. Even if we try to find ways around fundamental constraints, the tradeoffs show up somewhere.

The final requirement in order to take tradeoffs into account is that you really need to be able to let go of not being great at something. If you've chosen to prioritize your relationship with your kids over a clean house, then you need to be okay with letting other people see the mess. If you've prioritized physical activity over entertainment, you need to accept that other people are going to tease you for being ignorant of what's going on in the world. If you've chosen to focus on your career versus maintaining every friendship you've ever had, you need to get over the pang of hurt when people stop inviting you out.

Tradeoffs aren't always easy, which is probably why we try to avoid them.

Conclusion

If we think we can have it all, we're more likely to end up with nothing. We can get much farther if we decide where to focus our energy and which areas to ignore. When we actively choose which tradeoffs we want to make, we can feel much better about it than when we're forced to let things slide. We need to actively decide what we value the most. Each of the myriad decisions we make on a daily basis carries an opportunity cost. If we don't consider them, we easily end up stuck in situations where we're forgoing things we'd rather prioritize. We end up lamenting what we're missing out on against our will, unsure how this happened. But if we first consider the tradeoffs associated with the decisions we make, we can end up with far more satisfying choices.

144. Prisoner's Dilemma: What Game Are you Playing?

In this classic game theory experiment, you must decide: rat out another for personal benefit, or cooperate? The answer may be more complicated than you think.

What does it take to make people cooperate with each other when the incentives to act primarily out of self-interest are often so strong?

The Prisoner's Dilemma is a thought experiment originating from game theory. Designed to analyze the ways in which we cooperate, it strips away the variations between specific situations where people are called to overcome the urge to be selfish. Political scientist Robert Axelrod lays down its foundations in The Evolution of Cooperation:

Under what conditions will cooperation emerge in a world of egoists without a central authority? This question has intrigued people for a long time. And for good reason. We all know that people are not angels and that they tend to look after themselves and their own first. Yet we also know that cooperation does occur and that our civilization is based on it. But in situations where each individual has an incentive to be selfish, how can cooperation ever develop?

...To make headway in understanding the vast array of specific situations which have this property, a way is needed to represent what is common to these situations without becoming bogged down in the details unique to each...the famous Prisoner's Dilemma game.

The thought experiment goes as such: two criminals are in separate cells, unable to communicate, accused of a crime they both participated in. The police do not have enough evidence to sentence both without further evidence, though they are certain enough to wish to ensure they both spend time in prison. So they offer the prisoners a deal. They can accuse each other of the crime, with the following conditions:

- If both prisoners say the other did it, each will serve two years in prison.
- If one prisoner says the other did it and the other stays silent, the accused will serve three years and the accuser zero.
- If both prisoners stay silent, each will serve one year in prison.

In game theory, the altruistic behavior (staying silent) is called "cooperating," while accusing the other is called "defecting."

What should they do?

If they were able to communicate and they trusted each other, the rational choice is to stay silent; that way each serves less time in prison than they would otherwise. But how can each know the other won't accuse them? After all, people tend to act out of self-interest. The cost of being the one to stay silent is too high. The expected outcome when the game is played is that both accuse the other and serve two years. (In the real world, we doubt it would. After they served their time, it's not hard to imagine each of them still being upset. Two years is a lot of time for a spring to coil in a negative way. Perhaps they spend the rest of their lives sabotaging each other.)

The Iterated Prisoner's Dilemma

A more complex form of the thought experiment is the iterated Prisoner's Dilemma, in which we imagine the same two prisoners being in the same situation multiple times. In this version of the experiment, they are able to adjust their strategy based on the previous outcome.

If we repeat the scenario, it may seem as if the prisoners will begin to cooperate. But this doesn't make sense in game theory terms. When they know how many times the game will repeat, both have an incentive to accuse on the final round, seeing as there can be no

retaliation. Knowing the other will surely accuse on the final round, both have an incentive to accuse on the penultimate round—and so on, back to the start.

Gregory Mankiw summarizes how difficult it is to model cooperation in Business Economics as follows:

To see how difficult it is to maintain cooperation, imagine that, before the police captured . . . the two criminals, [they] had made a pact not to confess. Clearly, this agreement would make them both better off if they both live up to it, because they would each spend only one year in jail. But would the two criminals in fact remain silent, simply because they had agreed to? Once they are being questioned separately, the logic of self-interest takes over and leads them to confess. Cooperation between the two prisoners is difficult to maintain because cooperation is individually irrational.

However, cooperative strategies can evolve if we model the game as having random or infinite iterations. If each prisoner knows they will likely interact with each other in the future, with no knowledge or expectation their relationship will have a definite end, the cooperation becomes significantly more likely. If we imagine that the prisoners will go to the same jail or will run in the same circles once released, we can understand how the incentive for cooperation might increase. If you're a defector, running into the person you defected on is awkward at best, and leaves you sleeping with the fishes at worst.

Real-world Prisoner's Dilemmas

We can use the Prisoner's Dilemma as a means of understanding many real-world situations based on cooperation and trust. As individuals, being selfish tends to benefit us, at least in the short term. But when everyone is selfish, everyone suffers.

In The Prisoner's Dilemma, Martin Peterson asks readers to imagine two car manufacturers, Row Cars and Col Motors. As the only two actors in their market, the price each sells cars at has a direct connection to the price the other sells cars at. If one opts to sell at a higher price than the other, they will sell fewer cars as customers transfer. If one sells at a lower price, they will sell more cars at a lower profit margin, gaining customers from the other. In Peterson's example, if both set their prices high, both will make \$100 million per year. Should one decide to set their prices lower, they will make \$150 million while the other makes nothing. If both set low prices, both make \$20 million. Peterson writes:

Imagine that you serve on the board of Row Cars. In a board meeting, you point out that irrespective of what Col Motors decides to do, it will be better for your company to opt for low prices. This is because if Col Motors sets its price low, then a profit of \$20 million is better than \$0, and if Col Motors sets its price high, then a profit of \$150 million is better than \$100 million.

Gregory Mankiw gives another real-world example in Microeconomics, detailed here:

Consider an oligopoly with two members, called Iran and Saudi Arabia. Both countries sell crude oil. After prolonged negotiation, the countries agree to keep oil production low in order to keep the world price of oil high. After they agree on production levels, each country must decide whether to cooperate and live up to this agreement or to ignore it and produce at a higher level. The following image shows how the profits of the two countries depend on the strategies they choose.

Suppose you are the leader of Saudi Arabia. You might reason as follows:

I could keep production low as we agreed, or I could raise my production and sell more oil on world markets. If Iran lives up to the agreement and keeps its production low, then my country earns profit of \$60 billion with high production and \$50 billion with low production. In this case, Saudi Arabia is better off with high production. If Iran fails to live up to the agreement and produces at a high level, then my country earns \$40 billion with high production and \$30 billion with low production. Once again, Saudi Arabia is better off with high production. So, regardless of what Iran chooses to do, my country is better off reneging on our agreement and producing at a high level.

Producing at a high level is a dominant strategy for Saudi Arabia. Of course, Iran reasons in exactly the same way, and so both countries produce at a high level. The result is the inferior outcome (from both Iran and Saudi Arabia's standpoint) with low profits in each country. This example illustrates why oligopolies have trouble maintaining monopoly profits. The monopoly outcome is jointly rational for the oligopoly, but each oligopolist has an incentive to cheat. Just as self-interest drives the prisoners in the prisoners' dilemma to confess, self-interest makes it difficult for the oligopoly to maintain the cooperative outcome with low production, high prices and monopoly prices.

Other examples of prisoners' dilemmas include arms races, advertising, and common resources (see The Tragedy of the Commons). Understanding the Prisoner's Dilemma is an important component of the dynamics of cooperation, an extremely useful mental model.

Thinking of life as an iterative game changes how you play. Positioning yourself for the future carries more weight than "winning" in the moment.

144. The Tragedy Of The Commons

What is common to many is taken least care of, for all men have greater regard for what is their own than for what they possess in common with others. — Aristotle

The rules pay you to do the wrong thing. — Garrett Hardin

The Tragedy of the Commons is a parable that illustrates why common resources get used more than is desirable from the standpoint of society as a whole.

Garrett Hardin, introduces us to the The Tragedy of the Commons:

Picture a pasture open to all. It is to be expected that each herdsman will try to keep as many cattle as possible on the commons. Such an arrangement may work reasonably satisfactorily for centuries because tribal wars, poaching, and disease keep the numbers of both man and beast well below the carrying capacity of the land. Finally, however, comes the day of reckoning, that is, the day when the long-desired goal of social stability becomes a reality. At this point, the inherent logic of the commons remorselessly generates tragedy.

As a rational being, each herdsman seeks to maximize his gain. Explicitly or implicitly, more or less consciously, he asks, "What is the utility to me of adding one more animal to my herd?" This utility has one negative and one positive component.

1) The positive component is a function of the increment of one animal. Since the herdsman receives all the proceeds from the sale of the additional animal, the positive utility is nearly +1.

2) The negative component is a function of the additional overgrazing created by one more animal. Since, however, the effects of overgrazing are shared by all the herdsmen, the negative utility for any particular decision-making herdsman is only a fraction of 1.

Adding together the component partial utilities, the rational herdsman concludes that the only sensible course for him to pursue is to add another animal to his herd. And another; and another. . . . But this is the conclusion reached by each and every rational herdsman sharing a commons. Therein is the tragedy. Each man is locked into a system that compels him to increase his herd without limit—in a world that is limited. Ruin is the destination toward which all men rush, each pursuing his own best interest in a society that believes in the freedom of the commons. Freedom in a commons brings ruin to all.

Greg Mankiw, in his Microeconomics text says:

Consider life in a small medieval town. Of the many economic activities that take place in the town, one of the most important is raising sheep. Many of the town's families own flocks of sheep and support themselves by selling the sheep's wool, which is used to make clothing.

As our story begins, the sheep spend much of their time grazing on the land surrounding the town, called the Town Commons. No family owns the land. Instead the town residents own the land collectively, and all the residents are allowed to graze their sheep on it.

Collective ownership works well because land is plentiful. As long as everyone can get all the good grazing land they want, the Town Common is not a rival good and allowing residents' sheep to graze for free causes no problems. Everyone in the town is happy.

As the years pass, the population of the town grows and so does the number of sheep grazing on the Town Commons. With a growing number of sheep and a fixed amount of land, the land starts to lose its ability to replenish itself. Eventually, the land is grazed so heavily that it becomes barren. With no grass left on the Town Common, raising sheep is impossible, and the town's once prosperous wool industry disappears and, tragically, many families lose their source of livelihood.

What causes the tragedy? Why do the shepherds allow the sheep population to grow so large that it destroys the Town Common? The reason is that social and private incentives differ. Avoiding the destruction of the grazing land depends on the collective action of the shepherds. If the shepherds acted together, they could reduce the sheep population to a

size that the Town Common could support. Yet no single family has an incentive to reduce the size of its own flock because each flock represents only a small part of the problem. In essence, the Tragedy of the Commons arises because of an externality. When one family's flock grazes on the common land, it reduces the quality of the land available for other families. Because people neglect this negative externality when deciding how many sheep to own, the result is an excessive number of sheep.

If the tragedy had been foreseen, the town could have solved the problem in various ways. It could have regulated the number of sheep in each family's flock, internalized the externality by taxing sheep, or auctioned off a limited number of sheep grazing permits. That is, the medieval town could have dealt with the problem of overgrazing in the way that modern society deals with the problem of pollution.

In the case of land, however, there is a simpler solution. The town can divide up the land among town families. Each family can enclose its allotment of land with a fence and then protect it from excessive grazing. In this way, the land becomes a private good rather than a common resource. This outcome in fact occurred during the enclosure movement in England in the 17th century.

The Tragedy of the Commons is a story with a general lesson: when one person uses a common resource, he diminishes other people's enjoyment of it. Because of this negative externality, common resources tend to be used excessively. The government can solve the problem by reducing use of the common resource through regulation or taxes.

Alternatively, the government can sometimes turn the common resource into a private good.

This lesson has been known for thousands of years. The ancient Greek philosopher Aristotle pointed out the problem with common resources: 'What is common to many is taken least care of, for all men have greater regard for what is their own than for what they possess in common with others.'

145. Mental Models For a Pandemic

Mental models help us understand the world better, something which is especially valuable during times of confusion, like a pandemic. Here's how to apply mental models to gain a more accurate picture of reality and keep a cool head.

It feels overwhelming when the world changes rapidly, abruptly, and extensively. The changes come so fast it can be hard to keep up—and the future, which a few months ago seemed reliable, now has so many unknown dimensions. In the face of such uncertainty, mental models are valuable tools for helping you think through significant disruptions such as a pandemic.

A mental model is simply a representation of how something works. They are how we simplify complexity, why we consider some things more relevant than others, and how we reason. Using them increases your clarity of understanding, providing direction for the choices you need to make and the options you want to keep open.

Models for ourselves

During a pandemic, a useful model is “the map is not the territory.” In rapidly changing situations like a global health crisis, any reporting is an incomplete snapshot in time. Our maps are going to be inaccurate for many reasons: limited testing availability, poor reporting, ineffective information sharing, lack of expertise in analyzing the available information. The list goes on.

If past reporting hasn't been completely accurate, then why would you assume current reporting is? You have to be careful when interpreting the information you receive, using it as a marker to scope out a range of what is happening in the territory.

In our current pandemic, we can easily spot our map issues. There aren't enough tests available in most countries. Because COVID-19 isn't fatal for the majority of people who contract it, there are likely many people who get it but don't meet the testing criteria. Therefore, we don't know how many people have it.

When we look at country-level reporting, we can also see not all countries are reporting to the same standard. Sometimes this isn't a matter of “better” or “worse”; there are just different ways of collating the numbers. Some countries don't have the infrastructure for widespread data collection and sharing. Different countries also have different standards for what counts as a death caused by COVID-19.

In other nations, incentives affect reporting. Some countries downplay their infection rate so as to not create panic. Some governments avoid reporting because it undermines their political interests. Others are more worried about the information on the economic map than the health one.

Although it is important to be realistic about our maps, it doesn't mean we shouldn't seek to improve their quality. Paying attention to information from experts and ignoring unverified soundbites is one step to increasing the accuracy of our maps. The more accurate we can get them, the more likely it is that we'll be able to unlock new possibilities that help us deal with the crisis and plan for the future.

There are two models that we can use to improve the effectiveness of the maps we do have: “compounding” and “probabilistic thinking.”

Compounding is exponential growth, something a lot of us tend to have a poor intuitive grasp on. We see the immediate linear relationships in the situation, like how one test diagnoses one person, while not understanding the compounding effects of that relationship. Increased testing can lead to an exponential decrease in virus transmission because each infected person usually passes the virus onto more than just one other person.

One of the clearest stories to illustrate exponential growth is the story of the man who asked to be paid in rice. In this story, a servant is to be rewarded for his service. When

asked how he wanted to be paid, he asks to be paid in rice, using a chessboard to determine the final amount. Starting with one grain, the amount of rice is to be doubled for each square. One grain on the first square looks pathetic. But halfway through the chessboard, the servant is making a good yearly living. And after doubling the rice sixty-four times, the servant is owed more rice than the whole world can produce.

Improving our ability to think exponentially helps us understand how more testing can lead to both an exponential decrease in testing prices and an exponential increase in the production of those tests. It also makes clear just how far-reaching the impact of our actions can be if we don't take precautions with the assumption that we could be infected.

Probabilistic thinking is also invaluable in helping us make decisions based on the incomplete information we have. In the absence of enough testing, for example, we need to use probabilistic thinking to make decisions on what actions to pursue. We ask ourselves questions like: Do I have COVID-19? If there's a 1% chance I have it, is it worth visiting my grandparents?

Being able to evaluate reasonable probability has huge impacts on how we approach physical distancing. Combining the models of probabilistic thinking and map is not the territory suggests our actions need to be guided by infection numbers much higher than the ones we have. We are likely to make significantly different social decisions if we estimate the probability of infection as being three people out of ten instead of one person out of one thousand.

Bayesian updating can also help clarify the physical distancing actions you should take. There's a small probability of being part of a horrendous chain of events that might not just have poor direct consequences but also follow you for the rest of your life. Evaluating how responsible you are being in terms of limiting transmission, would you bet a loved one's life on it?

Which leads us to Hanlon's Razor. It's hard not to get angry at reports of beach parties during spring break or at the guy four doors down who has his friends over to hang out every night. For your own sanity, try using Hanlon's Razor to evaluate their behavior. They are not being malicious and trying to kill people. They are just exceptionally and tragically ignorant.

Finally, on a day-to-day basis, trying to make small decisions with incomplete information, you can use inversion. You can look at the problem backwards. When the best way forward is far from clear, you ask yourself what you could do to make things *worse*, and then avoid doing those things.

Models for society

Applying mental models aids in the understanding the dynamics of the large-scale social response.

Currently we are seeing the counterintuitive measures with first-order negatives (closing businesses) but second- and third-order positives (reduced transmission, less stress on the healthcare system). Second-order thinking is an invaluable tool at all times, including during a pandemic. It's so important that we encourage the thinking, analysis, and decision-making that factors in the effects of the effects of the decisions we make.

In order to improve the maps that our leaders have to make decisions, we need to sort through the feedback loops providing the content. If we can improve not only the feedback but also the pace of iterations, we have a better chance of making good decisions.

For example, if we improve the rate of testing and the speed of the results, it would be a major game-changer. Imagine if knowing whether you had the virus or not was a \$0.01 test that gave you a result in less than a minute. In that case, we could make different decisions about social openness, even in the absence of a vaccine (however, this may have invasive privacy implications, as tracking this would be quite difficult otherwise).

As we watch the pandemic and its consequences unfold, it becomes clear that leadership and authority are not the same thing. Our hierarchical instincts emerge strongly in times of

crisis. Leadership vacuums, then, are devastating, and disasters expose the cracks in our hierarchies. However, we also see that people can display strong leadership without needing any authority. A pandemic provides opportunities for such leadership to emerge at community and local levels, providing alternate pathways for meeting the needs of many. One critical model we can use to look at society during a pandemic is Ecosystems. When we think about ecosystems, we might imagine a variety of organisms interacting in a forest or the ocean. But our cities are also ecosystems, as is the earth as a whole.

Understanding system dynamics can give us a lot of insight into what is happening in our societies, both at the micro and macro level.

One property of ecosystems that is useful to contemplate in situations like a pandemic is resilience—the speed at which an ecosystem recovers after a disturbance. There are many factors that contribute to resilience, such as diversity and adaptability. Looking at our global situation, one factor threatening to undermine our collective resilience is that our economy has rewarded razor-thin efficiency in the recent past. The problem with thin margins is they offer no buffer in the face of disruption. Therefore, ecosystems with thin margins are not at all resilient. Small disturbances can bring them down completely. And a pandemic is not a small disturbance.

Some argue that what we are facing now is a Black Swan: an unpredictable event beyond normal expectations with severe consequences. Most businesses are not ready to face one. You could argue that an economic recession is *not* a black swan, but the particular shape of this pandemic is testing the resiliency of our social and economic ecosystems regardless. The closing of shops and business, causing huge disruption, has exposed fragile supply chains. We just don't see these types of events often enough, even if we know they're theoretically possible. So we don't prepare for them. We don't or can't create big enough personal and social margins of safety. Individuals and businesses don't have enough money in the bank. We don't have enough medical facilities and supplies. Instead, we have optimized for a narrow range of possibilities, compromising the resilience of systems we rely on.

Finally, as we look at the role national borders are playing during this pandemic, we can use the Thermodynamics model to gain insight into how to manage flows of people during and after restrictions. Insulation requires a lot of work, as we are seeing with our borders and the subsequent effect on our economies. It's unsustainable for long periods of time. Just like how two objects of different temperatures that come into contact with each other eventually reach thermal equilibrium, people will mix with each other. All borders have openings of some sort. It's important to extend planning to incorporate the realistic tendencies of reintegration.

Some final thoughts about the future

As we look for opportunities about how to move forward both as individuals and societies, Cooperation provides a useful lens. Possibly more critical to evolution than competition, cooperation is a powerful force. It's rampant throughout the biological world; even bacteria cooperate. As a species, we have been cooperating with each other for a long time. All of us have given up some independence for access to resources provided by others.

Pandemics are intensified because of connection. But we can use that same connectivity to mitigate some negative effects by leveraging our community networks to create cooperative interactions that fill gaps in the government response. We can also use the cooperation lens to create more resilient connections in the future.

Finally, we need to ask ourselves how we can improve our antifragility. How can we get to a place where we grow stronger through change and challenge? It's not about getting "back to normal." The normal that was our world in 2019 has proven to be fragile. We shouldn't *want* to get back to a time when we were unprepared and vulnerable.

Existential threats are a reality of life on earth. One of the best lessons we can learn is to open our eyes and integrate planning for massive change into how we approach our lives. This will not be the last pandemic, no matter how careful we are. The goal now should not be about assigning blame or succumbing to hindsight bias to try to implement rules designed to prevent a similar situation in the future. We will be better off if we make changes aimed at increasing our resilience and embracing the benefits of challenge.

146. Bad Arguments and How to Avoid Them

Productive arguments serve two purposes: to open our minds to truths we couldn't see — and help others do the same. Here's how to avoid common pitfalls and argue like a master.

We're often faced with situations in which we need to argue a point, whether we're pitching an investor or competing for a contract. When being powerfully persuasive matters, it's important that we don't use bad arguments that prevent useful debate instead of furthering it. To do this, it's useful to know some common ways people remove the possibility of a meaningful discussion. While it can be a challenge to keep our cool and not sink to using bad arguments when responding to a Twitter troll or during a heated confrontation over Thanksgiving dinner, we can benefit from knowing what to avoid when the stakes are high.

"If the defendant be a man of straw, who is to pay the costs?"

— Charles Dickens

To start, let's define three common types of bad arguments, or logical fallacies: "straw man," "hollow man," and "iron man."

Straw man arguments

A straw man argument is a misrepresentation of an opinion or viewpoint, designed to be as easy as possible to refute. Just as a person made of straw would be easier to fight with than a real human, a straw man argument is easy to knock to the ground. And just as it might look a bit like a real person from a distance, a straw man argument has the rough outline of the actual discussion. In some cases, it might seem similar to an outside observer. But it lacks any semblance of substance or strength. The sole purpose is for it to be easy to refute. It's not an argument you happen to find inconvenient or challenging. It's one that is logically flawed. A straw man argument may not even be invalid; it's just not relevant.

It's important not to confuse a strawman argument with a simplified summary of a complex argument. When we're having a debate, we may sometimes need to explain an opponent's grounds back to them to ensure we understand it. In this case, this explanation will be by necessity a briefer version. But it is only a straw man if the simplification is used to make it easier to attack, rather than to facilitate clearer understanding.

There are a number of common tactics used to construct straw man arguments. One is *per fas et nefas* (which means "through right and wrong" in Latin) and involves refuting one of the reasons for an opponent's argument, then claiming that discredits everything they've said. Often, this type of straw man argument will focus on an irrelevant or unimportant detail, selecting the weakest part of the argument. Even though they have no response to the rest of the discourse, they purport to have disproven it in its entirety. As Doug Walton, professor of philosophy at the University of Winnipeg, puts it, "The straw man tactic is essentially to take some small part of an arguer's position and then treat it as if that represented his larger position, even though it is not really representative of that larger position. It is a form of generalizing from one aspect to a larger, broader position, but not in a representative way."

Oversimplifying an argument makes it easier to attack by removing any important nuance. An example is the "peanut butter argument," which states life cannot have evolved through natural selection because we do not see the spontaneous appearance of new life forms inside sealed peanut butter jars. The argument claims evolutionary theory asserts life emerged through a simple combination of matter and heat, both of which are present in a jar of peanut butter. It is a straw man because it uses an incorrect statement about

evolution as being representative of the whole theory. The defender of evolution gets trapped into explaining a position they didn't even have: why life doesn't spontaneously develop inside a jar of peanut butter.

Another tactic is to over-exaggerate a line of reasoning to the point of absurdity, thus making it easier to refute. An example would be someone claiming a politician who is not opposed to immigration is thus in favor of open borders with no restrictions on who can enter a country. Seeing as that would be a weak view that few people hold, the politician then feels obligated to defend border controls and risks losing control of the debate and being charged as a hypocrite.

"The light obtained by setting straw men on fire is not what we mean by illumination."

— Adam Gopnik

Straw man arguments that respond to irrelevant points could involve *ad hominem* points, which are sort of relevant but don't refute the argument—for example, responding to the point that wind turbines are a more environmentally friendly means of generating energy than fossil fuels by saying, "But wind turbines are ugly." This point has a loose connection, yet the way wind turbines look doesn't discredit their benefits for power generation. A person who made an *ad hominem* point like that would likely be doing so because they knew they had no rebuttal for the actual assertion.

Quoting an argument out of context is another tactic of straw man arguments. "Quote mining" is the practice of removing any part of a source that proves contradictory, often using ellipses to fill in the gaps. For instance, film posters and book blurbs will sometimes take quotes from bad reviews out of context to make them seem positive. So, "It's amazing how bad this film is" becomes "Amazing," and "The perfect book for people who wish to be bored to tears" becomes "The perfect book." Reviewers face an uphill battle in trying not to write anything that could be taken out of control in this manner.

Hollow man arguments

A hollow man argument is similar to a straw man one. The difference is that it is a weak case attributed to a non-existent group. Someone will fabricate a viewpoint that is easy to refute, then claim it was made by a group they disagree with. Arguing against an opponent which doesn't exist is a pretty easy way to win any debate. People who use hollow man arguments will often favor vague, non-specific language without explicitly giving any sources or stating who their opponent is.

Hollow man arguments slip into debate because they're a lazy way of making a strong point without risking anyone refuting you or needing to be accountable for the actual strength of a line of reasoning. In Why We Argue (And How We Should): A Guide to Political Disagreement, Scott F. Aikin and Robert B. Talisse write that "speakers commit the hollow man when they respond critically to arguments that nobody on the opposing side has ever made. The act of erecting a hollow man is an argumentative failure because it distracts attention away from the actual reasons and argument given by one's opposition. . . . It is a full-bore fabrication of the opposition."

An example of a hollow man argument would be the claim that animal rights activists want humans and non-human animals to have a perfectly equal legal standing, meaning that dogs would have to start wearing clothes to avoid being arrested for public indecency. This is a hollow man because no one has said that all laws applying to humans should also apply to dogs.

"The smart way to keep people passive and obedient is to strictly limit the spectrum of acceptable opinion, but allow very lively debate within that spectrum."

Iron man argument

An iron man argument is one constructed in such a way that it is resistant to attacks by a challenger. Iron man arguments are difficult to avoid because they have a lot of overlap with legitimate debate techniques. The distinction is whether the person using them is doing so to prevent opposition altogether or if they are open to changing their minds and listening to an opposer. Being proven wrong is painful, which is why we often unthinkingly resort to shielding ourselves from it using iron man arguments.

Someone using an iron man argument often makes their own stance so vague that nothing anyone says about it can weaken it. They'll make liberal use of caveats, jargon, and imprecise terms. This means they can claim anyone who disagrees didn't understand them, or they'll rephrase their contention repeatedly. You could compare this to the language used in the average horoscope or in a fortune cookie. It's so vague that it's hard to disagree with or label it as incorrect because it *can't* be incorrect. It's like boxing with a wisp of steam.

An example would be a politician who answers a difficult question about their policies by saying, "I think it's important that we take the best possible actions to benefit the people of this country. Our priority in this situation is to implement policies that have a positive impact on everyone in society." They've answered the question, just without saying anything that anyone could disagree with.

Why bad arguments are harmful

What is the purpose of debate? Most of us, if asked, would say it's about helping someone with an incorrect, harmful idea see the light. It's an act of kindness. It's about getting to the truth.

But the way we tend to engage in debate contradicts our supposed intentions.
